The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

nWE is not asserted during a read cycle.

#### 1.1.5.3.6 GPMC\_CLK

GPMC\_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC\_CLK clock frequency is the GPMC\_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC\_CONFIG1\_i[1:0] GPMCFCLKDIVIDER bit field (where  $i = 0$  to 7), with a guaranteed 50-percent duty cycle.
- The GPMC\_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC.GPMC\_CONFIG1\_i[26:25] CLKACTIVATIONTIME field ( $i = 0$  to 7) defines the number of GPMC\_FCLK cycles from start access time to GPMC\_CLK activation.
- The GPMC\_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC\_CLK clock is kept low when access is defined as asynchronous.
- When cycle time completes, the GPMC\_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC\_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.
- When the GPMC is configured for synchronous mode, the GPMC\_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL\_PADCONF\_GPMC\_NCS7[24] INPUTENABLE1 = 1). GPMC\_CLK is looped back through the output and input buffers of the corresponding GPMC\_CLK pad at the OMAP boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

---

**Note:** To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
  - The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).
- 

#### 1.1.5.3.7 GPMC\_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC\_CLK edge can be controlled in the following ways:

- For the GPMC\_CLK signal, the GPMC.GPMC\_CONFIG1\_i[26:25] CLKACTIVATIONTIME field ( $i = 0$  to 7) allows setup and hold control of control-signal assertion time.

- The use of a divided GPMC\_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC\_CLK runs at the GPMC\_FCLK frequency so that GPMC\_CLK edge and control-signal transitions refer to the same GPMC\_FCLK edge, the control-signal transitions can be delayed by half of a GPMC\_FCLK period to provide minimum setup and hold times. This half-GPMC\_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC\_FCLK cycle.

#### 1.1.5.3.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently allowing nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters.

RDACCESSTIME is programmed in the GPMC.GPMC\_CONFIG5\_i[20:16] bit field (I = 0 to 7).

WRACCESSTIME is programmed in the GPMC.GPMC\_CONFIG6\_i[28:24] bit field (I = 0 to 7).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 31 GPMC\_FCLK cycles with a granularity of one (GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY = 0).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 62 GPMC\_FCLK cycles with a granularity of two (GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY = 1).

##### 1.1.5.3.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, RDACCESSTIME field (I = 0 to 7) defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater GPMC\_FCLK cycle value of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge corresponding to the GPMC\_CLK rising edge used for the first data capture.

GPMC\_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC\_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 1.1.5.4](#).

##### 1.1.5.3.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC\_CONFIG6\_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc\_wait pin is at a valid state two GPMC\_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 1.1.5.4](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC\_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 1.1.5.4](#).

#### 1.1.5.3.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

PAGEBURSTACCESSTIME is programmed in the GPMC.GPMC\_CONFIG5\_i[27:24] bit field (I = 0 to 7).

PAGEBURSTACCESSTIME can be set from 0 to 15 GPMC\_FCLK cycles with a granularity of one (GPMC.GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY set to 0), or from 0 to 30 GPMC\_FCLK cycles with a granularity of two (TIMEPARAGRANULARITY set to 1).

#### 1.1.5.3.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater GPMC\_FCLK cycle value of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC\_FCLK edge on read access. For details about wait monitoring, see [Section 1.1.5.4](#).

#### 1.1.5.3.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC\_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 1.1.5.4](#).

#### 1.1.5.3.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

### 1.1.5.4 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc\_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC four input wait pins: gpmc\_wait3, gpmc\_wait2, gpmc\_wait1, and gpmc\_wait0. These four pins allow direct plugin and control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC.GPMC\_CONFIG1\_i[17:16] WAITPINSELECT field (I = 0 to 7) selects which input gpmc\_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC.GPMC\_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured by CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC.GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC.GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC\_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC.GPMC\_CONFIG1\_i[29] READTYPE and GPMC.GPMC\_CONFIG1\_i[27] WRITETYPE bits).

#### 1.1.5.4.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC\_CONFIG1\_I[19:18] WAITMONITORINGTIME field (I = 0 to 7).

---

##### Notes:

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
  - This extra delay is expressed as a number of GPMC\_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC\_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.
- 

Figure 1-8 shows wait behavior during an asynchronous single read access.

**Figure 1-8. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)**

gpmc-008

**Note:** The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

#### 1.1.5.4.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC.GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC\_CONFIG1\_i[19:18] WAITMONITORINGTIME fields (I = 0 to 7).

**Notes:**

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC\_CLK clock cycles, even though the access is defined as synchronous, and even though no clock is provided to the external device. Still, GPMC\_CONFIG1\_i[1:0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

#### 1.1.5.4.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC\_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC\_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC.GPMC\_CONFIG1\_i[19:18] WAITMONITORINGTIME field (where I = 0 to 7), and is expressed as a number of GPMC\_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC.GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

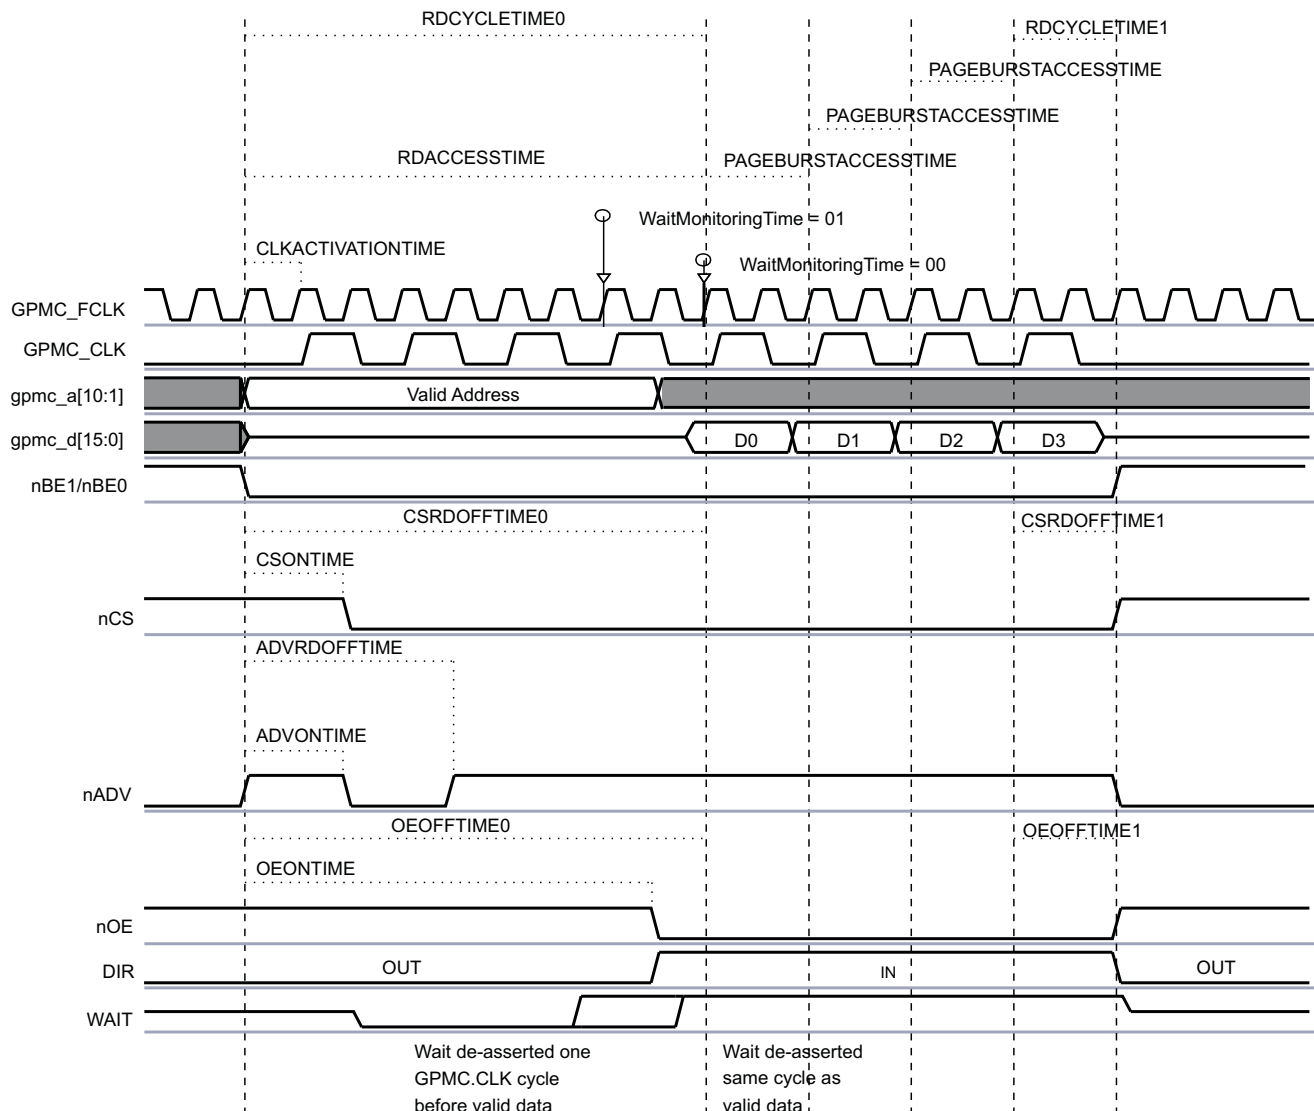

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 ( at RDACCESSTIME completion)
- In the WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC\_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME ≠ 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 1-9 shows wait behavior during a synchronous read burst access.

**Figure 1-9. Wait Behavior During a Synchronous Read Burst Access**

gpmc-009

**Note:** The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

#### 1.1.5.4.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC\_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to control the effective memory device GPMC\_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- The WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC\_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME ≠ 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

---

**Note:** Wait monitoring is supported for all configurations except for GPMC\_CONFIG1\_i[19:18] WAITMONITORINGTIME = 0x 0 (where I = 0 to 7) for write bursts with a clock divider of 1 or 2 (GPMC\_CONFIG1\_i[1:0] GPMCFCLKDIVIDER field equal to 0x0 or 0x1 respectively).

---

#### 1.1.5.4.5 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 1.1.5.14.2, NAND Device-Ready Pin](#).

#### 1.1.5.4.6 Idle Cycle Control between Successive Accesses

##### 1.1.5.4.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device (that is, control the nCS/nOE de-assertion to data bus in high-impedance delay) must be delayed.

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time (whichever occurs first) and delays the next access start-cycle time. It is programmed through the GPMC.GPMC\_CONFIG6\_i[3:0] BUSTURNAROUND bit field (where I = 0 to 7).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

##### 1.1.5.4.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMEECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC.GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMEECSEN bit (I = 0 to 7) enables insertion of a minimum number of GPMC\_FCLK cycles, defined by the GPMC.GPMC\_CONFIG6\_i[11:8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMEECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during Word32 or burst accesses split into successive single accesses when the single-access mode is used (GPMC\_CONFIG1\_i[30] READMULTIPLE = 0 or GPMC\_CONFIG1\_i[28] WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC\_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

#### 1.1.5.4.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If GPMC\_CONFIG6\_i[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC\_FCLK cycles.

**Note:** CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in GPMC\_CONFIG6\_i registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See [Section 1.1.5.4.6.1](#) for more details on bus turnaround.

[Table 1-3](#) describes the configuration required for idle cycle insertion.

**Table 1-3. Idle Cycle Insertion Configuration**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BTA cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BTA cycles are inserted.
R	> 0	W	Any	Any	0	0	BTA cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).

**Table 1-3. Idle Cycle Insertion Configuration (continued)**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

#### 1.1.5.4.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC.GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit (where I stands for the GPMC chip-select value, I = 0 to 7). Increasing all access timing parameters allows support of slow devices.

#### 1.1.5.5 gpmc\_io\_dir Pin

The gpmc\_io\_dir pin is used to control I/O direction on the GPMC data bus gpmc\_d[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the OMAP35x Applications Processor, if required.

The gpmc\_io\_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc\_io\_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc\_io\_dir pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
  - The gpmc\_io\_dir pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
  - After an asynchronous read access, the gpmc\_io\_dir pin goes from IN to OUT at RDACCESSTIME + 1 GPMC\_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the gpmc\_io\_dir pin goes from IN to OUT at RDACCESSTIME + 2 GPMC\_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc\_io\_dir pin is OUT (see [Section 1.1.5.3.10, Bus Keeping Support](#)).

To prevent unnecessary toggling, the gpmc\_io\_dir pin stays IN between two successive read accesses to a nonmultiplexed device (address mapping supports nonmultiplexed 16-bit wide devices with limited address (2 Kbytes)).

[Figure 1-10](#) shows address mapping in nonmultiplexed mode with a limited address range (A[10:1]).

#### 1.1.5.6 Reset

No reset signal is sent to the external memory device by the GPMC. The PRCM specifications provide more information about external-device reset.

The PRCM module provides an input pin, global\_rst\_n, to the GPMC:

- The global\_rst\_n pin is activated during OMAP warm reset and cold reset.
- The global\_rst\_n pin initializes the internal state-machine and the internal configuration registers.

#### 1.1.5.7 Write Protect (nWP)

When connected to the attached memory device, the WRITE PROTECT signal can enable or disable the lockdown function of the attached memory.

The gpmc\_nwp output pin value is controlled through the GPMC.GPMC\_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

#### 1.1.5.8 Byte Enable (nBE1/nBE0)

BYTE ENABLE signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

### 1.1.5.9 Asynchronous Access Description

In asynchronous operations:

- GPMC\_CLK is not provided outside the GPMC.
- GPMC\_CLK is kept low.

#### 1.1.5.9.1 Asynchronous Single Read

##### 1.1.5.9.1.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 1-10 shows an asynchronous single read operation on a nonmultiplexed device.

**Figure 1-10. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device**

gpmc-010

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC\_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC\_CONFIG1\_i register settings:
  - GPMC\_CONFIG1\_i[30] READMULTIPLE bit at 0 (read single access)
  - GPMC\_CONFIG1\_i[29] READTYPE bit at 0 (asynchronous read)
  - GPMC\_CONFIG1\_i[9] MUXADDDATA bit at 0 (non multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3:0] CS ONTIME field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12:8] CSRD OFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3:0] ADV ONTIME field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12:8] ADV RD OFFTIME field.

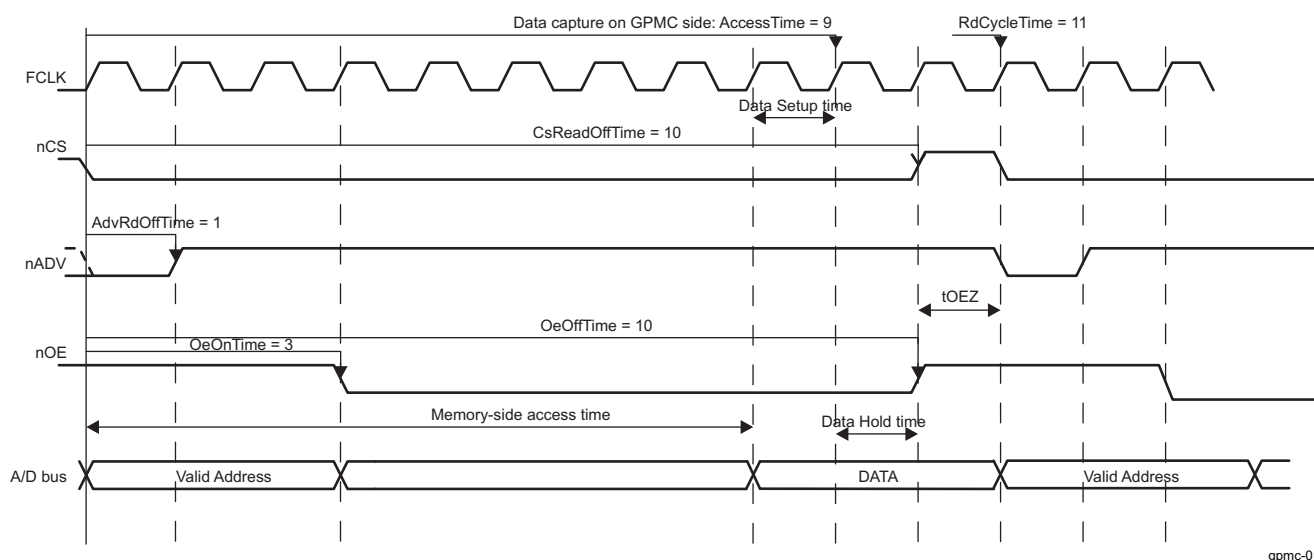

- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12:8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC.GPMC\_CONFIG5\_i[20:16] RDACCESSTIME field.
- The end of the access is defined by the RDCYCLETIME parameter. The read cycle time is defined in the GPMC.GPMC\_CONFIG5\_i[4:0] RDCYCLETIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 1.1.5.3.10, Bus Keeping Support](#) for more details.

#### 1.1.5.9.1.2 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 1-11 shows an asynchronous single read operation on an address/data-multiplexed device.

**Figure 1-11. Asynchronous Single Read on an Address/Data-Multiplexed Device**

gpmc-011

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 1.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.GPMC\_CONFIG1\_i register settings (I = 0 to 7):

- READMULTIPLE bit at 0 (read single access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits ([16:1] from a GPMC perspective, [15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits [25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as nonmultiplexed accesses.

### 1.1.5.9.2 Asynchronous Single Write

#### 1.1.5.9.2.1 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 1-12 shows an asynchronous single write operation on a nonmultiplexed device.

**Figure 1-12. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device**

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC\_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC\_CONFIG1\_i register settings:
  - WRITEMULTIPLE bit at 0 (write single access)
  - WRITETYPE bit at 0 (write asynchronous)
  - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[3:0] CSWROFFTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[3:0] ADVWROFFTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[20:16] ADVWROFFTIME field.

Address and data are driven on their corresponding buses at start-of-cycle time.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[19:16] WEONTIME field.
  - nWE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[28:24] WEONTIME field.
- Direction signal DIR:
  - DIR signal is OUT during the entire access.

- The end of the access is defined by the WRCYCLETIME parameter.  
This write-cycle time is defined in the GPMC.GPMC\_CONFIG5\_i[12:8] WRCYCLETIME field.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 1.1.5.3.10, Bus Keeping Support](#).

In the GPMC, when a 16-bit wide device is attached to the controller, a Word32 write access is split into two Word16 write accesses. For more information about GPMC access size and type adaptation, see [Section 1.1.5.2.7, System Burst Versus External Device Burst Support](#).

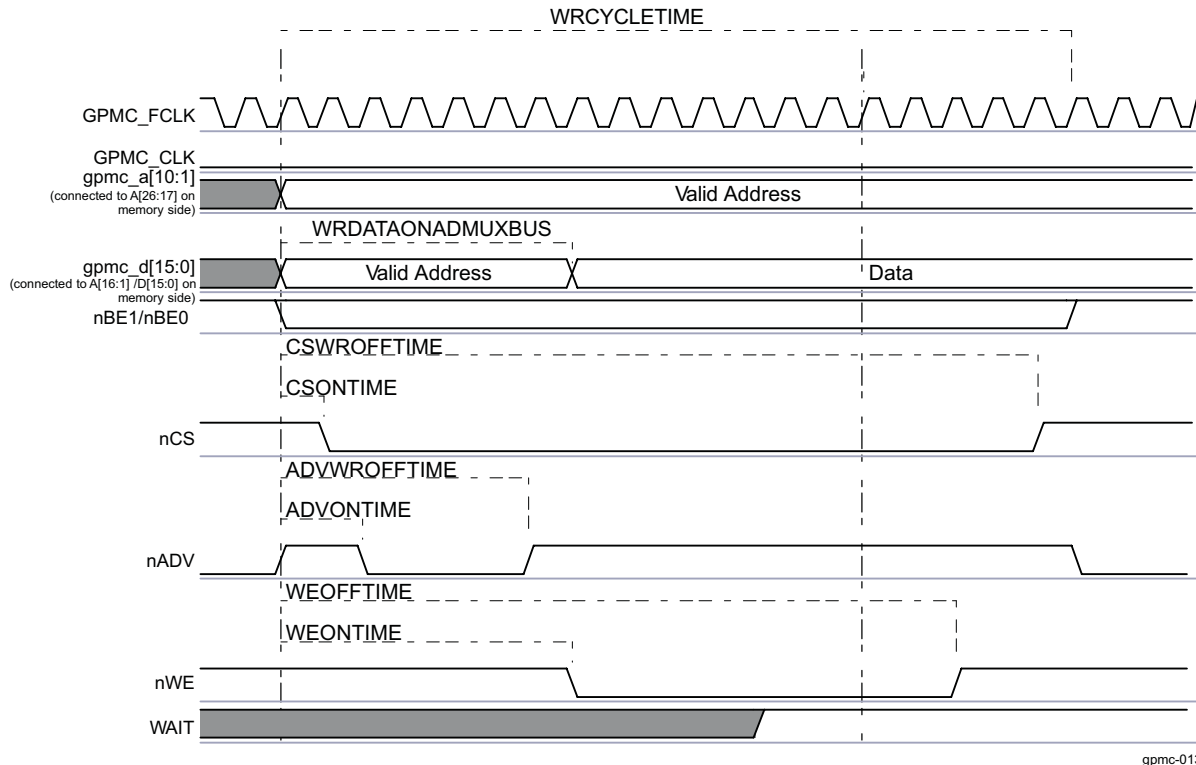

Between two successive accesses, if an nCS pulse is needed:

- The GPMC.GPMC\_CONFIG6\_i[11:8] CYCLE2CYCLEDELAY field can be programmed with GPMC.GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

#### 1.1.5.9.2.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

[Figure 1-13](#) shows an asynchronous single write operation on an address/data-multiplexed device.

**Figure 1-13. Asynchronous Single Write on an Address/Data-Multiplexed Device**

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address on the address/data muxed bus until WRDATAONADMUXBUS time, and then it drives the data. For more information, see [Section 1.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.GPMC\_CONFIG1\_i register settings (I = 0 to 7):

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 0 (write asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at the start of cycle time, and the remaining address bits [26:17] are placed on the address bus.

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

Data is driven on the address/data bus at a GPMC\_CONFIG6\_i[19:16] WRDATAONADMUXBUS time.

**Note:** Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

### 1.1.5.9.3 Asynchronous Multiple (Page Mode) Read

Figure 1-14 shows an asynchronous multiple read operation.

**Note:** The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

For read access with GPMC.GPMC\_CONFIG1\_i register settings:

- READMULTIPLE bit at 1 (read multiple access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 0 (non-address/data-multiplexed device). The page mode is not supported by address/data-multiplexed devices.

In Figure 1-14, two Word32 read host accesses on the GPMC configured with READMULTIPLE = 1, READTYPE = 0, and MUXADDDATA = 0 are merged into one multiple-read access (page mode of four Word16) on the attached device.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[3:0] CSONTIME field and ensures the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[12:8] CSRDOFFTIME field and ensures the address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by the RDACCESSTIME parameter.  
The access time is defined in the GPMC.GPMC\_CONFIG5\_i[20:16] RDACCESSTIME field.

During consecutive accesses, the GPMC increments the address after each data read completes.

- Delay between successive read data in the page is controlled by the PAGEBURSTACCESSTIME parameter:
  - This timing is defined in the GPMC.GPMC\_CONFIG5\_i[27:24] PAGEBURSTACCESSTIME field.
  - Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.
- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion plus the time from RDACCESSTIME to CSRDOFFTIME.
  - The read cycle time is defined in the GPMC.GPMC\_CONFIG5\_i[4:0] RDCYCLETIME field.
  - In [Figure 1-14](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).
- Direction signal DIR:
  - DIR goes from OUT to IN at the same time as nOE assertion time.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 1.1.5.3.10](#), *Bus Keeping Support*.

### 1.1.5.10 Synchronous Access

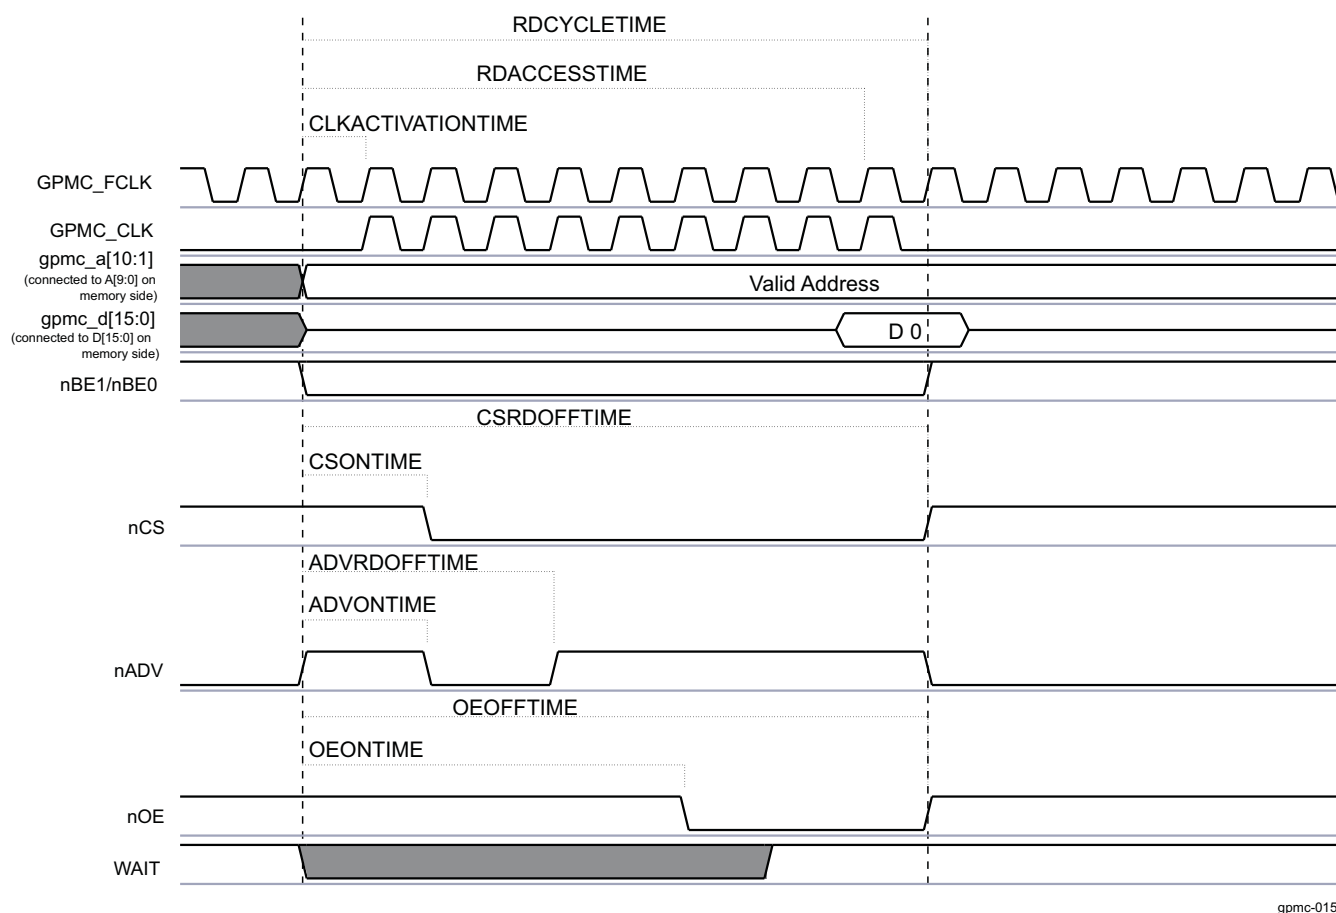

In synchronous operations:

- The GPMC\_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC\_CLK clock is derived from the GPMC\_FCLK clock using the GPMC.GPMC\_CONFIG1\_i[1:0] GPMCFCLKDIVIDER field (where I = 0 to 7).
- The GPMC.GPMC\_CONFIG1\_i[26:25] CLKACTIVATIONTIME field specifies that the GPMC\_CLK is provided outside the GPMC 0, 1, or 2 GPMC\_FCLK cycles after start access time until CycleTime completes.
- When the GPMC is configured for synchronous mode, the GPMC\_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL\_PADCONF\_GPMC\_NCS7[24] INPUTENABLE1 = 1). GPMC\_CLK is looped back through the output and input buffers of the corresponding GPMC\_CLK pad at the OMAP boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

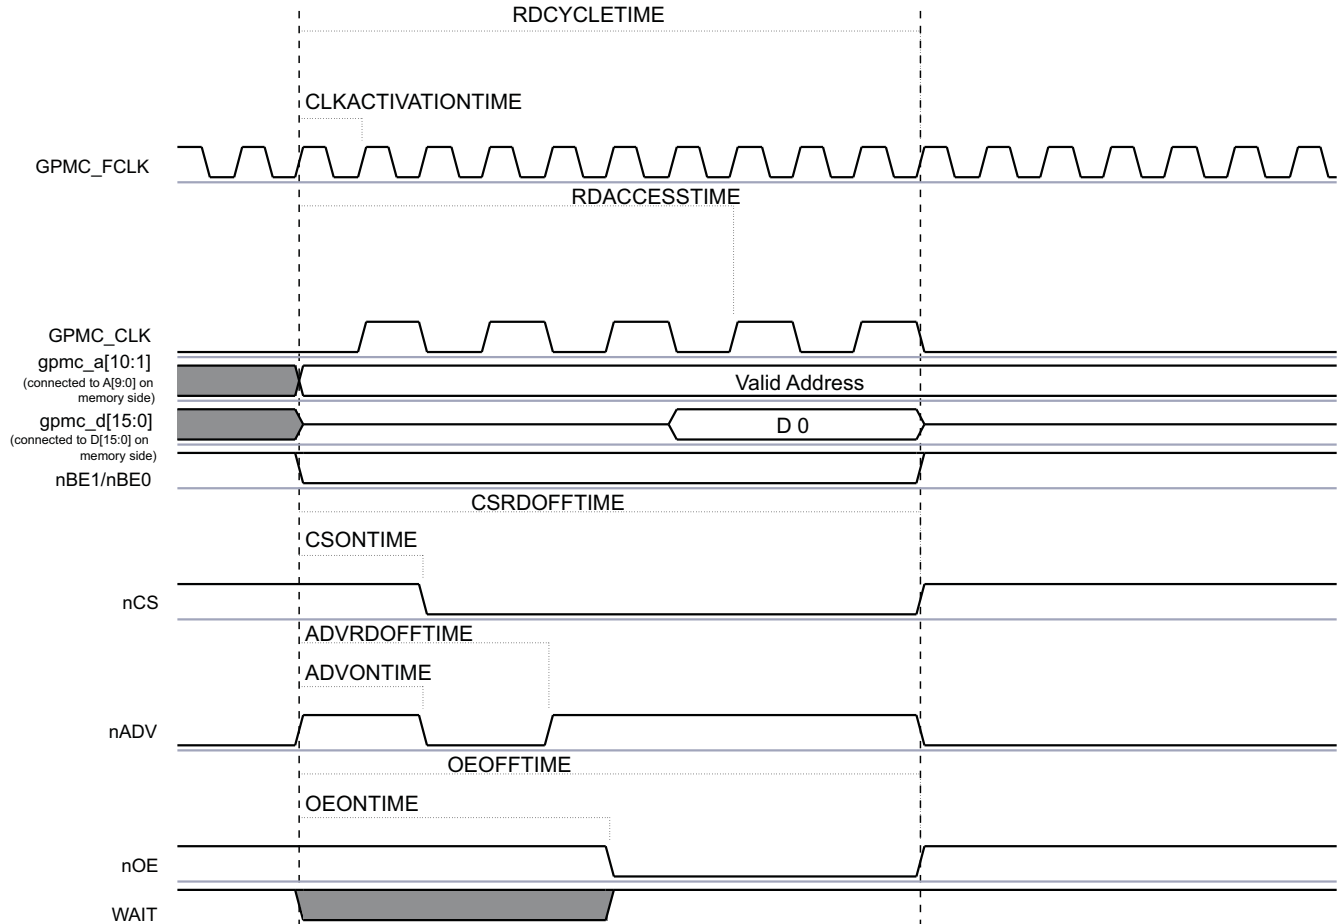

#### 1.1.5.10.1 Synchronous Single Read

Figure 1-15 and Figure 1-16 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

**Figure 1-15. Synchronous Single Read (GPMCFCLKDIVIDER = 0)**

gpmc-015

**Figure 1-16. Synchronous Single Read (GPMCFCLKDIVIDER = 1)**

gpmc-016

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC\_CONFIG1\_ *i* register settings:
  - READMULTIPLE bit at 0 (read single access)
  - READTYPE bit at 1 (read synchronous)
  - MUXADDDATA bit at 0 (non-address/data-multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_ *i*[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC\_CONFIG2\_ *i*[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_ *i*[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_ *i*[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_ *i*[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_ *i*[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC\_CONFIG5\_ *i*[20:16]

RDACCESSTIME or by monitoring the WAIT signal.

- Total access time (GPMC.GPMC\_CONFIG5\_i[4:0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSWROFFTIME.
- Direction signal DIR:  
DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 1.1.5.3.10, Bus Keeping Support](#).

### 1.1.5.10.2 Synchronous Single Write

**Figure 1-17. Synchronous Single Write on an Address/Data-Multiplexed Device**

gpmc-017

**Note:** The WAIT signal is active low.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus until WRDATAONADMUXBUS time (GPMC\_CONFIG6\_i[19:16]).

The GPMC.GPMC\_CONFIG1\_i register settings (I = 0 to 7) are as follows:

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 1 (write synchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at cycle-start time, and the remaining address bits [26:17] are placed on the address bus.

The address phase ends at WRDATAONADMUXBUS.

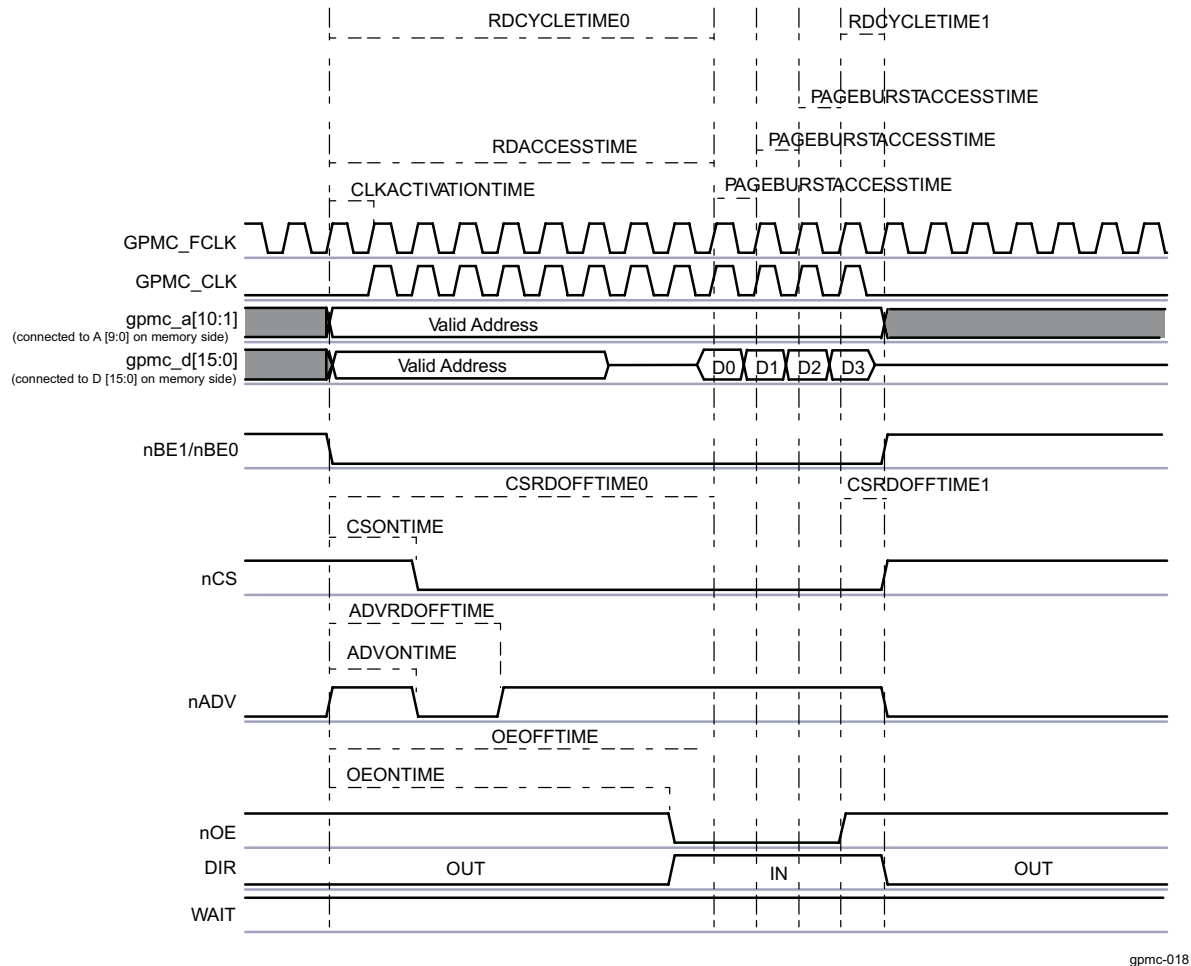

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

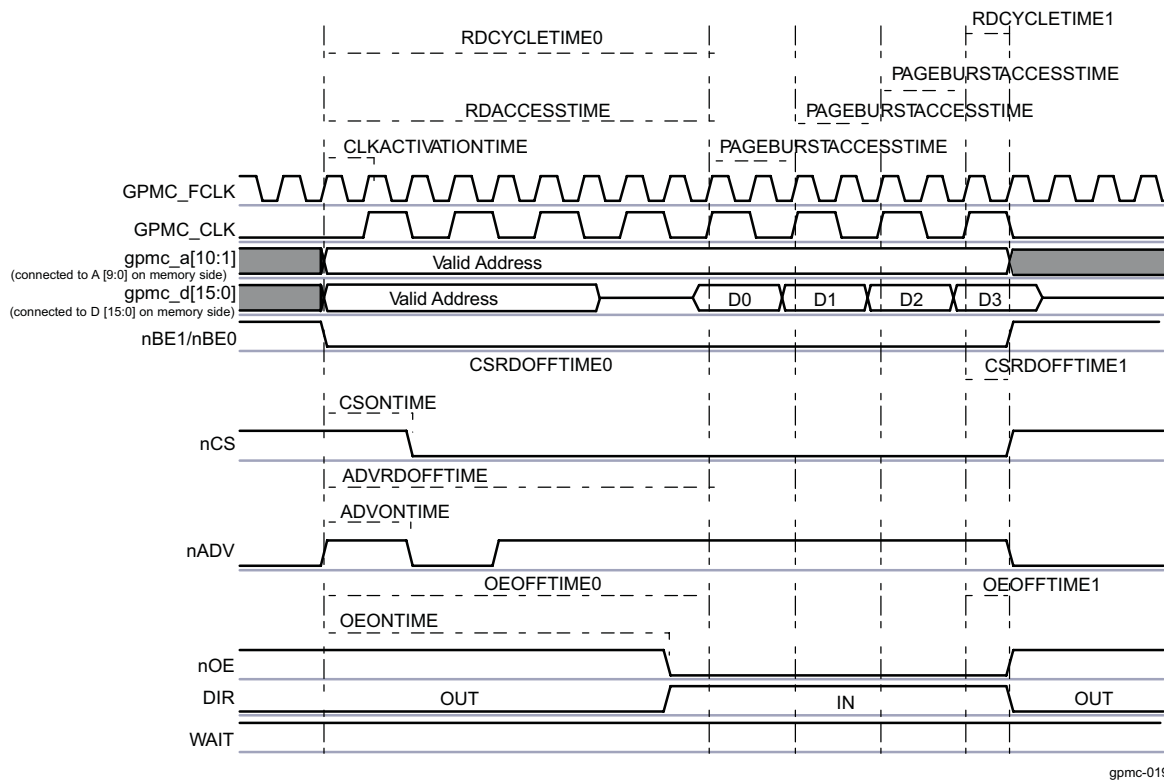

### 1.1.5.10.3 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word 16 Burst with Wraparound Capability)

Figure 1-18 and Figure 1-19 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

**Figure 1-18. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)**

**Note:** The WAIT signal is active low.

**Figure 1-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)**

NOTE: The WAIT signal is active low.

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC\_CONFIG1\_ *i* register settings:
  - READMULTIPLE bit at 1 (read multiple access)
  - READTYPE bit at 1 (read synchronous)
  - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_ *i*[3:0] CSOFTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC\_CONFIG2\_ *i*[12:8] CSRDOFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_ *i*[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_ *i*[12:8] ADVRDOFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_ *i*[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_ *i*[12:8] OEOFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC\_CONFIG5\_ *i*[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Successive read data are provided by the memory device each one or two GPMC\_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Depending on the device page length, the GPMC can control device page crossing during a new burst request and purposely insert initial latency.

- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus the time from RDACCESSTIME to CSRDOFFTIME.
  - RDCYCLETIME is defined in the GPMC.GPMC\_CONFIG5\_i register.
  - In [Figure 1-19](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 + RDCYCLETIME1.
- Direction signal DIR:
  - DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 1.1.5.3.10, Bus Keeping Support](#).

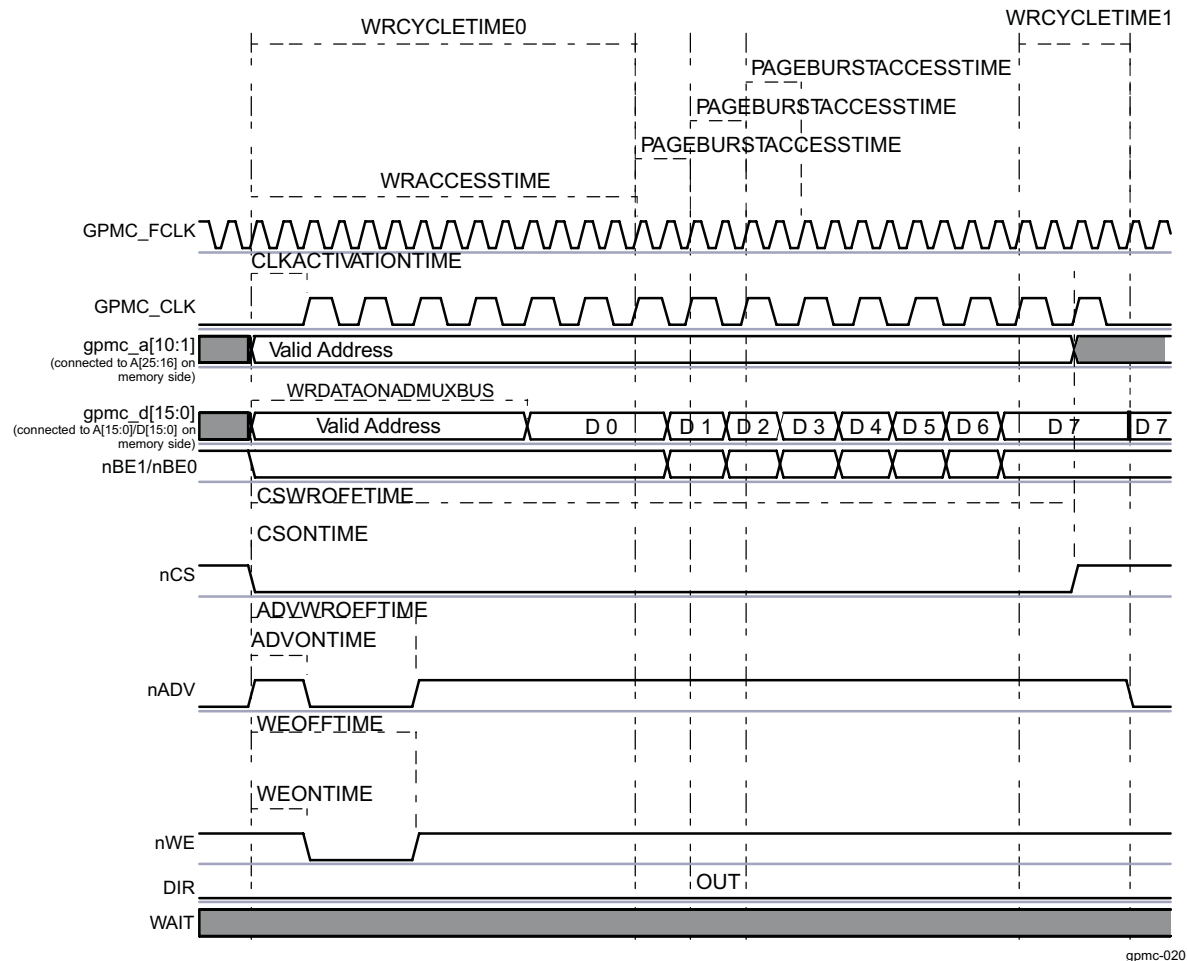

- Burst wraparound
  - The GPMC.GPMC\_CONFIG1\_i[31] WRAPBURST bit allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary.

#### 1.1.5.10.4 Synchronous Multiple (Burst) Write

Burst write mode provides synchronous single or consecutive accesses.

[Figure 1-20](#) shows a synchronous multiple (burst) write.

**Figure 1-20. Synchronous Multiple (Burst) Write**

NOTE: The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC\_CONFIG1\_i register settings:
  - WRITEMULTIPLE bit at 1 (write multiple access)
  - WRITETYPE bit at 1 (write synchronous)
  - MUXADDDATA bit at 1 (address/data-multiplexed device)

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC.GPMC\_CONFIG2\_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[20:16] ADVWROFFTIME field.
- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[19:16] WEONTIME field.
  - nWE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[28:24] WEOFFTIME field.

---

**Note:** The nWE falling edge must not be used to control the time when the burst first data is driven in the address / data bus because some new devices require the nWE signal at low during the address phase.

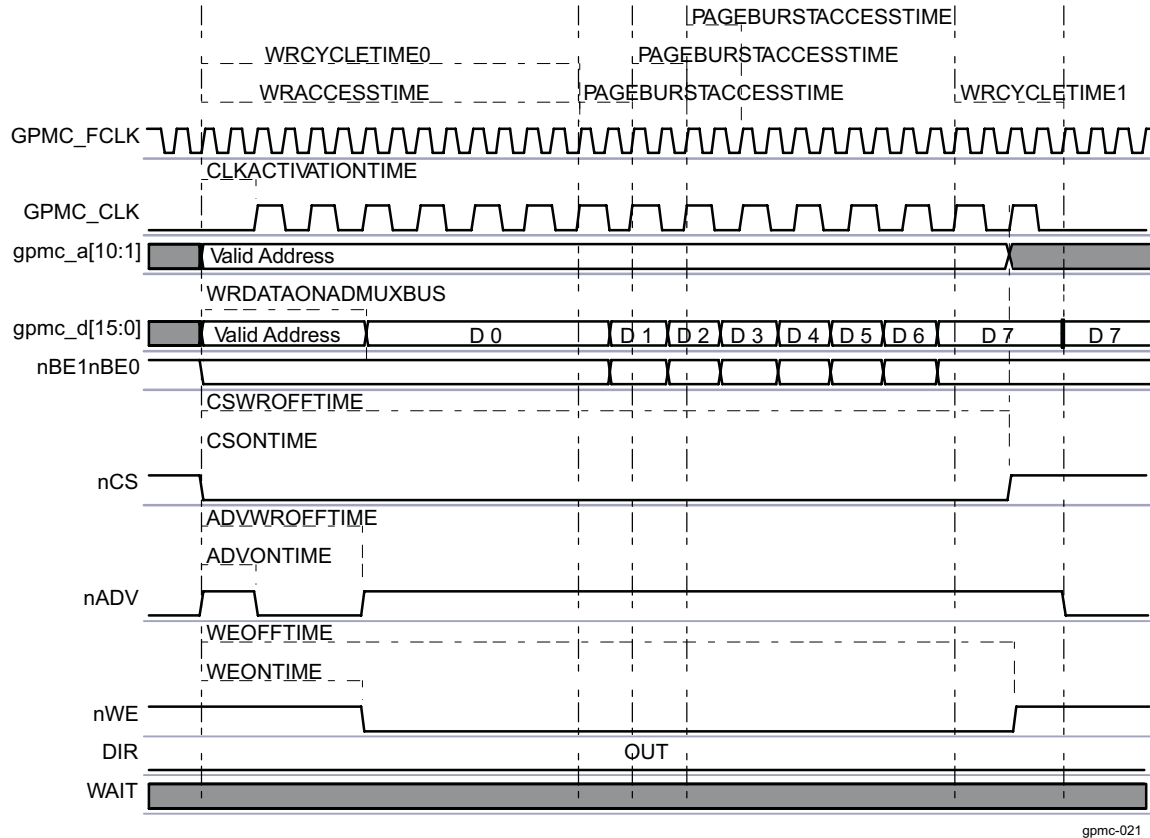

---

- First write data is driven by the GPMC at WRDATAONADMUXBUS (GPMC\_CONFIG6\_i[19:16]), when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during PAGEBURSTACCESSTIME GPMC\_FCLK cycles. The last data of the synchronous burst write is driven until WRCYCLETIME completes.
  - WRACCESSTIME is defined in the GPMC.GPMC\_CONFIG5\_i register.
  - The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.
- Total access time (WRCYCLETIME) corresponds to WRACCESSTIME plus the address hold time from nCS deassertion, plus time from WRACCESSTIME to CSWROFFTIME.
  - WRCYCLETIME is defined in the GPMC.GPMC\_CONFIG5\_i register.
  - In [Figure 1-20](#), the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1.
- Direction signal DIR:
  - DIR is OUT during the entire access.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 1.1.5.3.10, Bus Keeping Support](#).

[Figure 1-21](#) shows the same synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

**Figure 1-21. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode**

The first data of the burst is driven on the a/d bus at GPMC\_CONFIG6\_i[19:16] WRDATAONADMUXBUS.

### 1.1.5.11 pSRAM Basic Programming Model

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. These devices can be accessed by the GPMC with the GPMC.GPMC\_CONFIG1\_i[11:10] DEVICETYPE field (I = 0 to 7).

The pSRAM devices support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

In both pSRAM cases, the GPMC configuration for this chip-select must be set according to the specifications of the attached device.

### 1.1.5.12 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC.GPMC\_ERR\_TYPE register and the address of the illegal access is stored in the GPMC.GPMC\_ERR\_ADDRESS register. The GPMC only keeps the first error abort information until the GPMC.GPMC\_ERR\_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC.GPMC\_ERR\_TYPE[0] ERRORVALID bit.

- **ERRORNOTSUPPADD** occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.
- **ERRORNOTSUPPMCMD** occurs when an unsupported command request is decoded at the L3 interconnect interface.
- **ERRORTIMEOUT**: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC.GPMC\_TIMEOUT\_CONTROL register and enabled with the GPMC.GPMC\_TIMEOUT\_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

### 1.1.5.13 Boot Configuration

See [Section 1.1.3.3.2, GPMC CS0 Default Configuration at IC Reset](#).

### 1.1.5.14 NAND Device Basic Programming Model

NAND (8-bit and 16-bit) memory devices using a classical NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to chip enable don't care NAND devices since the chip-select allocated to the NAND device has to be de-asserted if accesses to other chip-selects are requested.

#### 1.1.5.14.1 NAND Memory Device in Byte or Word16 Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or Word16).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

### 1.1.5.14.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC.GPMC\_CONFIG7\_i register (where  $i = 0$  to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

#### CAUTION

To allow correct command, address, and data-access controls, the GPMC.GPMC\_CONFIG1\_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in [Table 1-4](#). Failure to comply with these settings corrupts the NAND interface protocol.

**Table 1-4. Chip-Select Configuration for NAND Interfacing**

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] <sup>(1)</sup>	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9]	0	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

<sup>(1)</sup>  $i = 0$  to 7

The GPMC.GPMC\_CONFIG1\_i to GPMC.GPMC\_CONFIG4\_i register (where  $i = 0$  to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

### 1.1.5.14.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The CPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC.GPMC\_NAND\_COMMAND\_i and GPMC.GPMC\_NAND\_ADDRESS\_i register locations (I = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC.GPMC\_NAND\_COMMAND\_i register location and to the GPMC.GPMC\_NAND\_ADDRESS\_i register location must be posted for faster operations (I = 0 to 7). The GPMC.GPMC\_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC.GPMC\_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

GPMC.GPMC\_NAND\_COMMAND\_i and GPMC.GPMC\_NAND\_ADDRESS\_i (I = 0 to 7) are Word32 locations, which means any Word32 or Word16 access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use Word32 or Word16 access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to GPMC.GPMC\_NAND\_COMMAND\_i and GPMC.GPMC\_NAND\_ADDRESS\_i can be used, and any of the four byte locations of the registers are valid.

The same applies to a GPMC.GPMC\_NAND\_COMMAND\_i and a GPMC.GPMC\_NAND\_ADDRESS\_i (I = 0 to 7) Word32 write access to a 16-bit wide NAND device (split into two Word16 accesses). In the case of a Word16 write access, the MSByte of the Word16 value must be set according to the NAND device requirement (usually 0). Either Word16 location or any one of the four byte locations of the registers is valid.

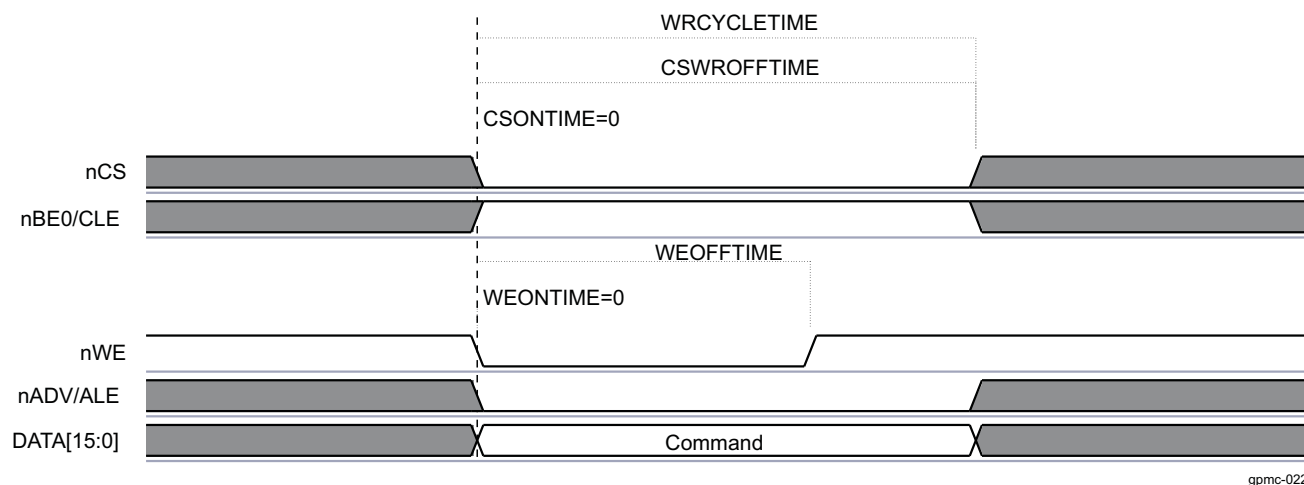

### 1.1.5.14.1.3 Command Latch Cycle

Writing data at the GPMC.GPMC\_NAND\_COMMAND\_i location (i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 1-22 shows the NAND command latch cycle.

**Figure 1-22. NAND Command Latch Cycle**

**Note:** CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

#### 1.1.5.14.1.4 Address Latch Cycle

Writing data at the GPMC.GPMC\_NAND\_ADDRESS\_i location ( $i = 0$  to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 1-23 shows the NAND address latch cycle.

**Figure 1-23. NAND Address Latch Cycle**

**Note:** ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

#### 1.1.5.14.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC.GPMC\_NAND\_DATA\_i location (I = 0 to 7) mapped in the chip-select-associated control register region. GPMC.GPMC\_NAND\_DATA\_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC.GPMC\_NAND\_DATA\_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and OMAP IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 1-24 shows the NAND data read cycle.

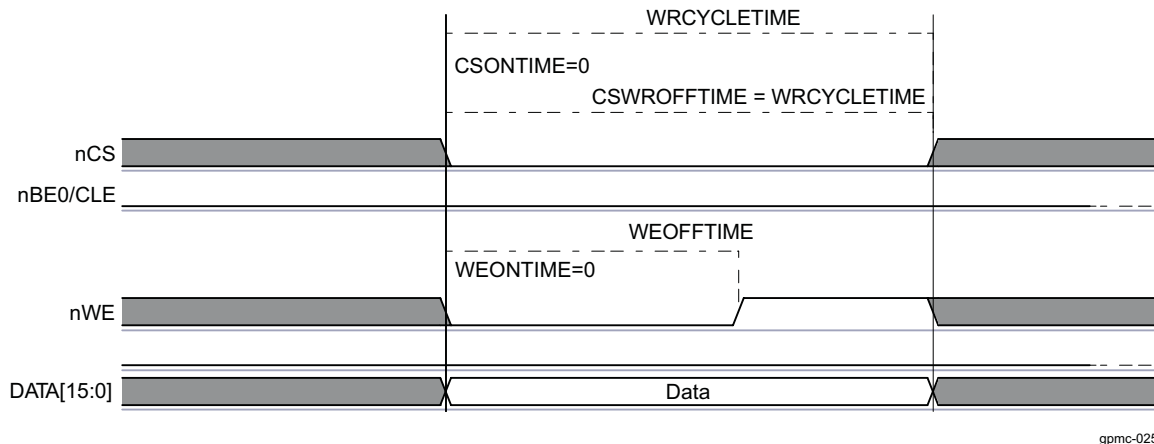

Figure 1-24. NAND Data Read Cycle

Writing data to the GPMC.GPMC\_NAND\_DATA\_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 1-25 shows the NAND data write cycle.

**Figure 1-25. NAND Data Write Cycle**

gpmc-025

#### 1.1.5.14.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 1.1.5.14.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

#### 1.1.5.14.1.7 Read and Write Access Size Adaptation

##### 1.1.5.14.1.7.1 8-bit Wide NAND Device

Host Word16 and Word32 read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

##### 1.1.5.14.1.7.2 16-bit Wide NAND Device

Host Word32 read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write Word16 accesses to the NAND memory device. Word16 access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a Word16 basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or Word16 read access gets the next Word16 NAND location. For a write access, the invalid byte part of the Word16 is driven to FF, and the next byte or Word16 write access programs the next Word16 NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

#### 1.1.5.14.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the four WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONTORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 s) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

---

**Note:** If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC.GPMC\_CONFIG1\_I[21] WAITWRITEMONTORING and GPMC.GPMC\_CONFIG1\_I[22] WAITREADMONTORING bits to 0, where I = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 3) of the GPMC\_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC.GPMC\_IRQENABLE register bits[11:8]).

Even if the READWAITMONTORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC\_STATUS register.

The READWAITMONTORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

---

##### 1.1.5.14.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC.GPMC\_STATUS WAITxSTATUS bit (x = 0 to 3). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

##### 1.1.5.14.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc\_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC.GPMC\_CONFIG WAITxPINPOLARITY bits (x = 0 to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1

to the WAITxEDGEDETECTIONSTATUS bit ( $x = 0$  to  $3$ ) of the GPMC.GPMC\_IRQSTATUS register according to the gpmc\_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC\_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC.GPMC\_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC\_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC\_IRQSTATUS register according to the gpmc\_wait pin used for the NAND device ready signal monitoring.

### 1.1.5.14.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations.

The user can choose from two different algorithms with different error correction capabilities, Hamming code (for 1-bit error code correction) and BCH code (for 4- or 8-bit error correction) through the GPMC\_ECC\_CONFIG[16] ECCALGORITHM bit. Only one ECC context can be active at any given time through the GPMC\_ECC\_CONFIG[3:1] ECCCS bit. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

#### 1.1.5.14.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or Word16 read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

##### 1.1.5.14.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC.GPMC\_ECCj\_RESULT,  $j = 1$  to  $9$ ) to store ECC computation results when the specified number of bytes or Word16s has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The GPMC.GPMC\_ECCj\_RESULT register value is valid only when the programmed number of bytes or Word16s has been accumulated, which means that the same number of bytes or Word16s has been read from or written to the NAND device in sequence.

The GPMC.GPMC\_ECC\_CONTROL[3:0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The GPMC.GPMC\_ECCj\_RESULT register value ( $j = 1$  to 9) can be considered valid when ECCPOINTER equals  $j + 1$ . When GPMC.GPMC\_ECCj\_RESULT (where  $j = 9$ ) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC.GPMC\_ECC\_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC.GPMC\_ECCj\_RESULT register,  $j = 1$  to 9), the number of bytes or Word16s used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSISE bits ( $j = 1$  to 9) in the GPMC.GPMC\_ECC\_SIZE\_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC.GPMC\_ECCj\_RESULT).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or Word16s used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or Word16s used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 Word16, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC.GPMC\_ECCj\_RESULT registers ( $j$ ) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSISE bits are set to 0, and the ECC9RESULTSISE bit is set to 1.

#### 1.1.5.14.3.1.2 ECC Enabling

The GPMC.GPMC\_ECC\_CONFIG[3:0] ECCCS field selects the allocated chip-select. The GPMC.GPMC\_ECC\_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSISE (where  $j = 1$  to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 1-5 describes the ECC enable settings.

**Table 1-5. ECC Enable Settings**

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-7	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE0
ECCjRESULTSISE ( $j$ from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

### 1.1.5.14.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 1-26 and Figure 1-27. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

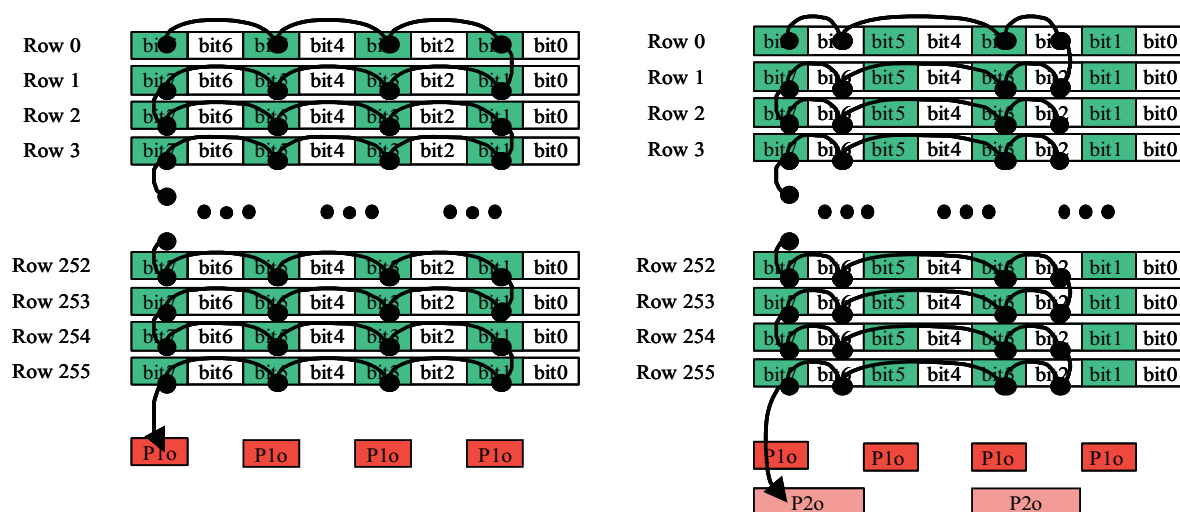

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

**Figure 1-26. Hamming Code Accumulation Algorithm ()**

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

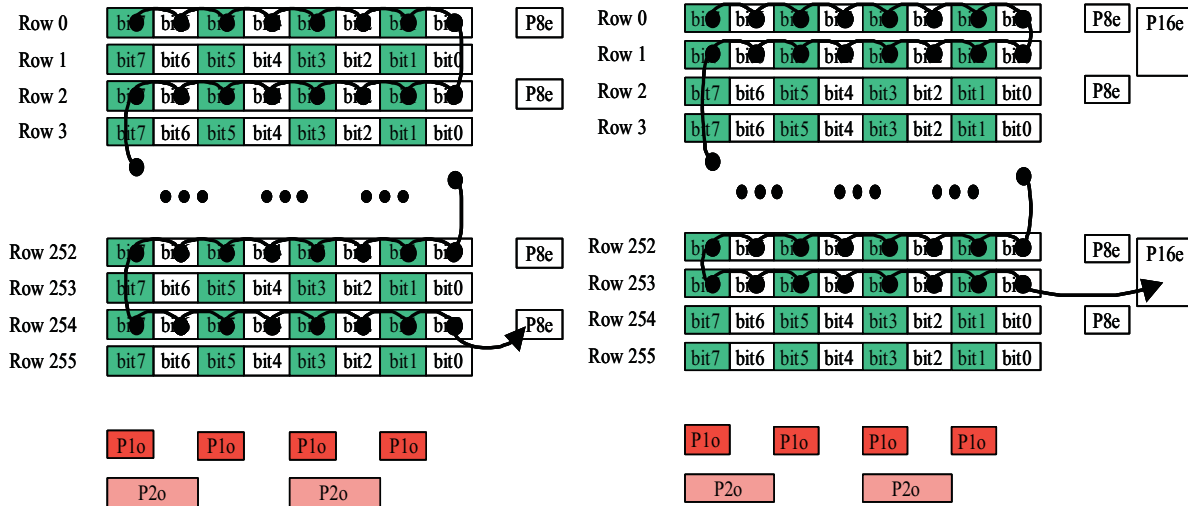

P8e = row0 XOR row2 XOR row4 XOR XOR row254

P8o = row1 XOR row3 XOR row5 XOR XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR XOR row254 XOR row 255

Figure 1-27. Hamming Code Accumulation Algorithm (2/2)

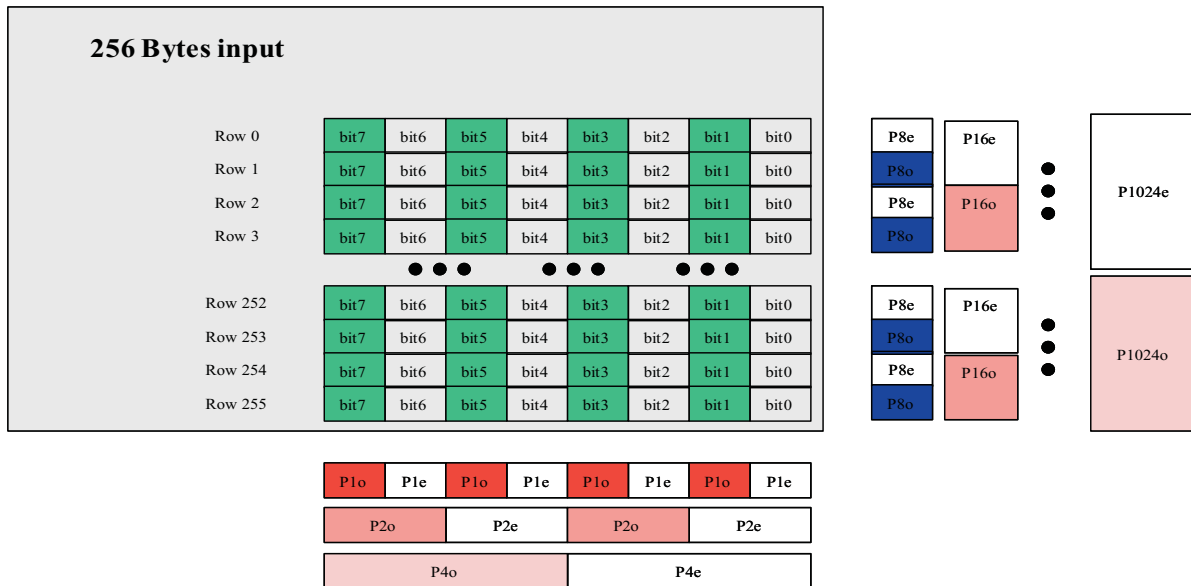

gpmc-027

Unused parity bits in the result registers are set to 0.

Figure 1-28 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 1-28. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 1-29 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

**Figure 1-29. ECC Computation for a 512-Byte Data Stream (Read or Write)**

gpmc-029

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC\_ECCj\_RESULT registers ( $j = 1$  to 9).

#### 1.1.5.14.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

#### 1.1.5.14.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

#### 1.1.5.14.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC.GPMC\_ECC\_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. [Figure 1-30](#) and [Figure 1-31](#) show a 128 Word 16 ECC computation scheme and a 256 Word 16 ECC computation scheme.

Figure 1-30. 128 Word 16 ECC Computation

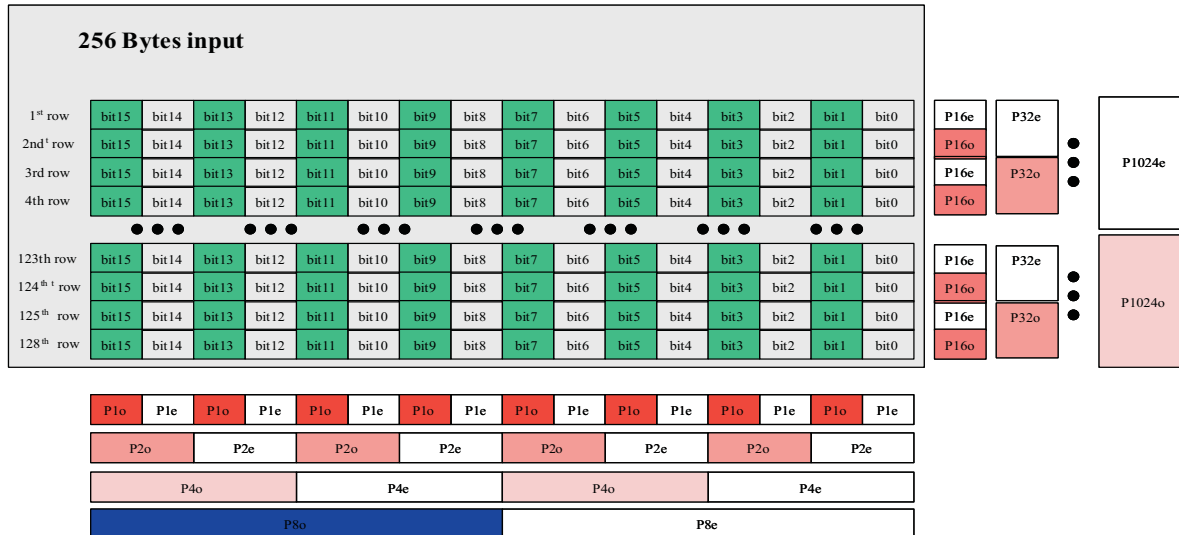

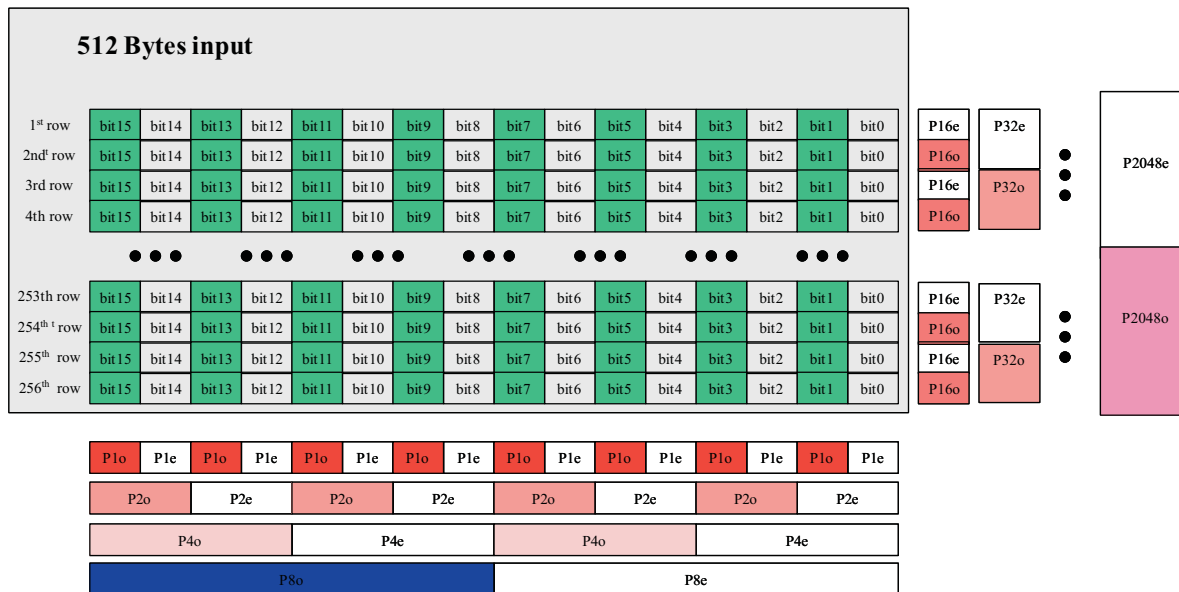

Figure 1-31. 256 Word 16 ECC Computation

### 1.1.5.14.3.2 BCH Code

All references to Error Code Correction (ECC) in this subsection refer to the 4- or 8-bit error correction BCH code.

#### 1.1.5.14.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses. Typical page write sequence:
  - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
  - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a

- second, separate phase. The ECC module is disabled during that time.
  - NAND writes its cache line (page) to the array.
- Typical page read sequence:
- Sequential read of a page. ECC is calculated on the fly.
  - ECC module buffers status determines the presence of errors.
2. Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
  3. Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to  $8 \times 512$ -byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.  
The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
  4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
  5. The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

#### 1.1.5.14.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message  $M(x)$ . In our standard case, 512 bytes of data (that is,  $2^{12}$  bits = 4096 bits) are seen as a polynomial of degree  $2^{12} - 1 = 4095$ , with parameters ranging from  $M_0$  to  $M_{4095}$ . For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction. The ECC is a remainder polynomial  $R(x)$  of degree 103 (or 51, depending on the selected mode). The complete codeword  $C(x)$  is the concatenation of  $M(x)$  and  $R(x)$  as shown in [Table 1-6](#).

**Table 1-6. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)**

	Message $M(x)$			ECC $R(x)$		
Bit number	$M_{4095}$	...	$M_0$	$R_{103}$	...	$R_0$

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message  $M(x)$  of degree  $((512 + 3) * 8) - 1 = 4119$ , for a total of  $3 + 13 = 16$  spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in GPMC\_BCH\_RESULT0\_i, GPMC\_BCH\_RESULT1\_i, GPMC\_BCH\_RESULT2\_i, and GPMC\_BCH\_RESULT3\_i (where  $i = 0$  to 7).

#### 1.1.5.14.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte  $b_7$ - $b_0$  (with  $b_0$  the LS bit) represents a segment of polynomial  $b_7 * x^{(7+i)} + b_6 * x^{(6+i)} + \dots + b_0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.

- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

**Note:** The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2<sup>12</sup>-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

**Table 1-7. Aligned Message Byte Mapping in 8-bit NAND**

Byte offset	8-bit word
0x000	(msb) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (lsb)

**Table 1-8. Aligned Message Byte Mapping in 16-bit NAND**

Byte offset	16-bit words MSB	16-bit words LSB
0x000	Byte 510 (0x1FE)	(msb) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

**Table 1-9. Aligned Nibble Mapping of Message in 8-bit NAND**

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (lsb)

**Table 1-10. Misaligned Nibble Mapping of Message in 8-bit NAND**

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
$(S+1)/2 - 2$	Nibble 2	Nibble 1
$(S+1)/2 - 1$	Nibble 0 (lsb)	

**Table 1-11. Aligned Nibble Mapping of Message in 16-bit NAND**

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$S/2 - 4$	Nibble 5	Nibble 4	Nibble 7	Nibble 6
$S/2 - 2$	Nibble 1	Nibble 0 (lsb)	Nibble 3	Nibble 2

**Table 1-12. Misaligned Nibble Mapping of Message in 16-bit NAND (1 Unused Nibble)**

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S+1)/2 - 4$	Nibble 4	Nibble 3	Nibble 6	Nibble 5
$(S+1)/2 - 2$	Nibble 0 (lsb)		Nibble 2	Nibble 1

**Table 1-13. Misaligned Nibble Mapping of Message in 16-bit NAND (2 Unused Nibbles)**

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S+2)/2 - 4$	Nibble 3	Nibble 2	Nibble 5	Nibble 4
$(S+2)/2 - 2$			Nibble 1	Nibble 0 (lsb)

**Table 1-14. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibbles)**

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S+3)/2 - 4$	Nibble 2	Nibble 1	Nibble 4	Nibble 3
$(S+3)/2 - 2$			Nibble 0 (lsb)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

#### 1.1.5.14.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 ½ bytes) from the module's interface, then store them to the NAND's spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a software-controlled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error has been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

#### 1.1.5.14.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 1.1.5.14.3.2.3](#).

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the module's behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for  $t = 4$  ECC, where ECC is 6 ½ bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

#### 1.1.5.14.3.2.2.3.1 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

---

**Note:** In the following figures size and size0 are the same parameter.

---

**Figure 1-32. Manual Mode Sequence and Mapping**

gpmc-032

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

#### 1.1.5.14.3.2.2.3.2 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 1.1.5.14.3.2.2.3.3 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

#### 1.1.5.14.3.2.2.3.4 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 1.1.5.14.3.2.2.3.5 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 1.1.5.14.3.2.2.3.6 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 1.1.5.14.3.2.2.3.7 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

#### 1.1.5.14.3.2.2.3.8 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 1.1.5.14.3.2.2.3.9 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

#### 1.1.5.14.3.2.2.3.10 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 1.1.5.14.3.2.2.3.11 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

#### 1.1.5.14.3.2.2.3.12 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

### 1.1.5.14.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 1.1.5.14.3.2.2.1](#).

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

A table on the left summarizes the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of  $n = 2^{13} - 1 = 8191$  bits. That codeword (higher-order bits) is all-zero and implicit during computations.

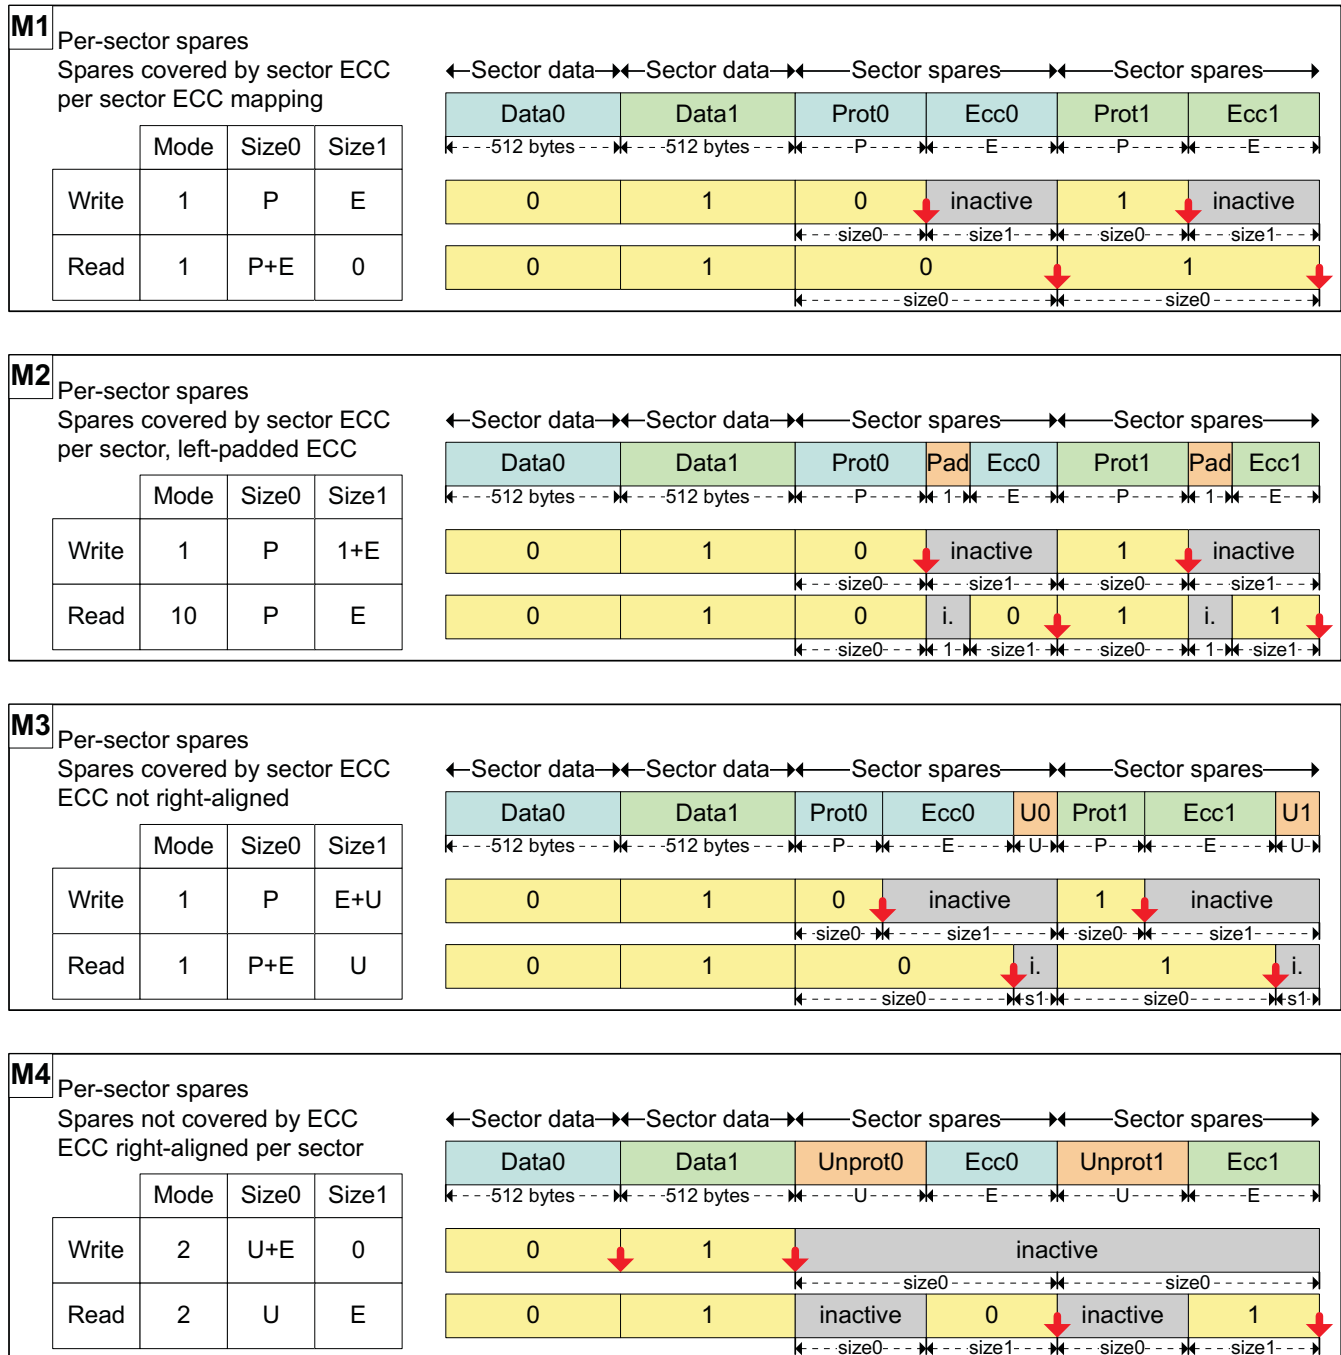

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - all sectors:  $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - sector 0 codeword:  $(512) + P + E$
  - other sectors:  $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - all codewords  $(512) + E$

#### 1.1.5.14.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

**Figure 1-33. NAND Page Mapping and ECC: Per-Sector Schemes**

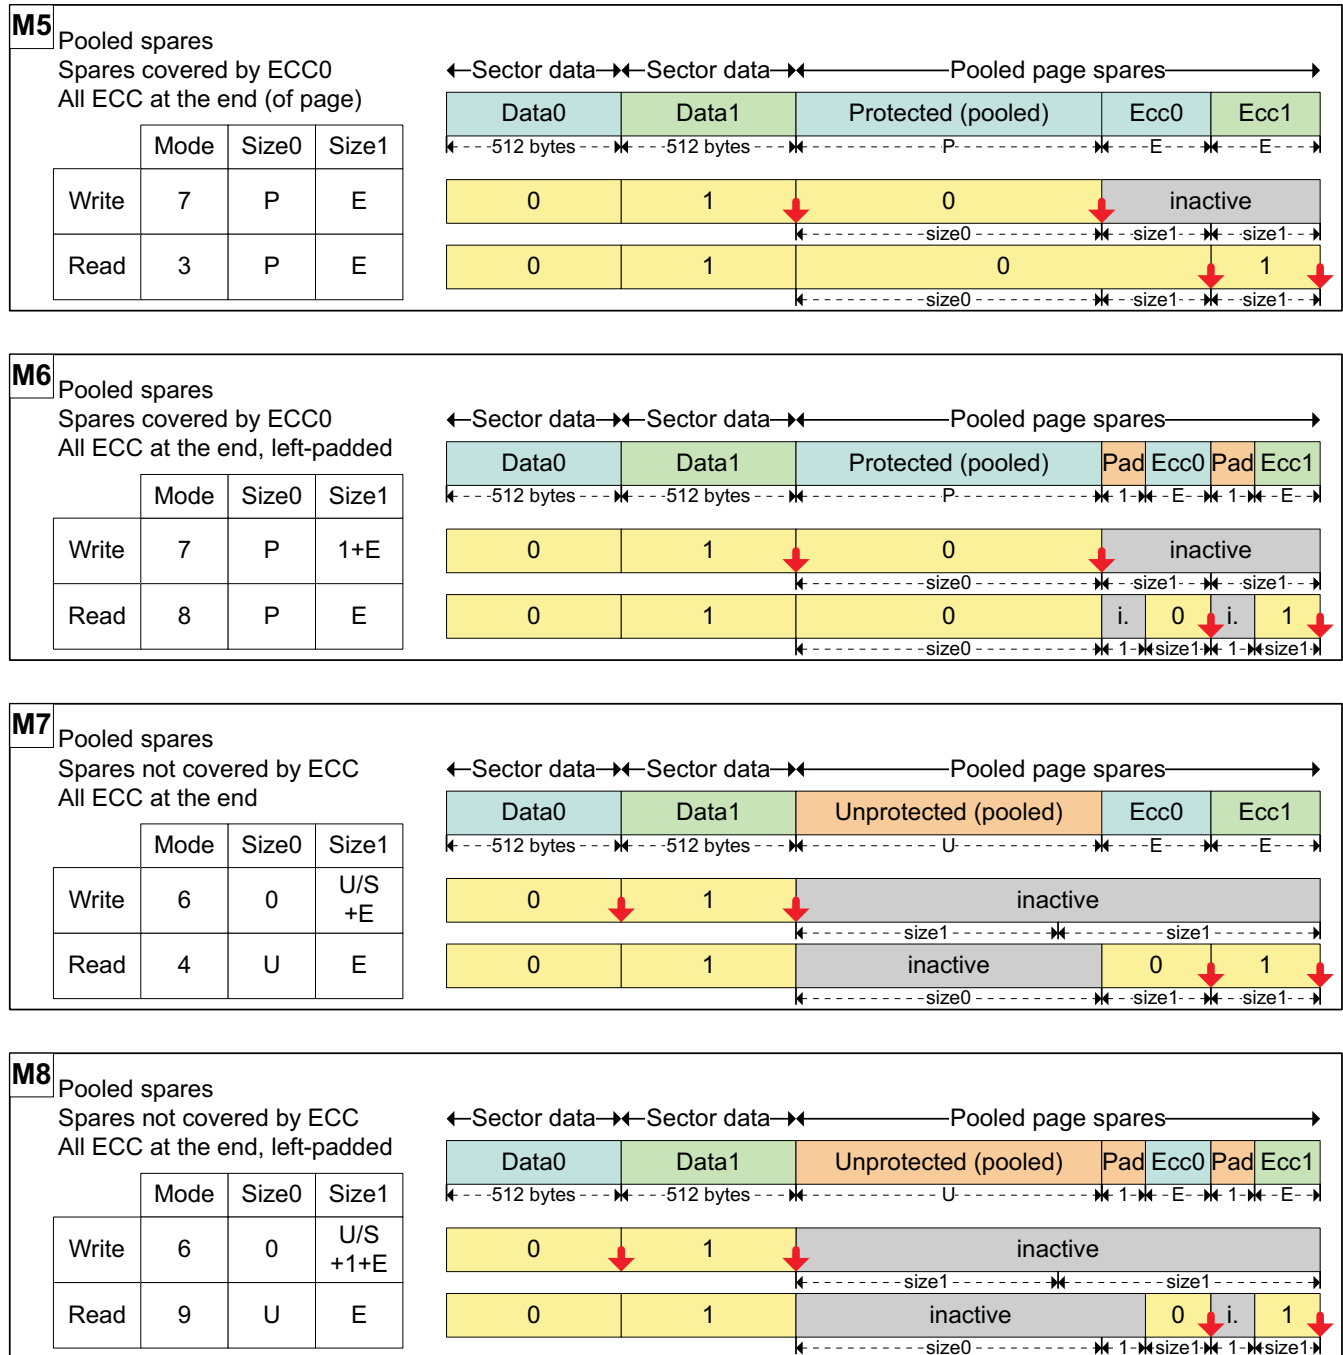

gpmc-033

### 1.1.5.14.3.2.3.2 Pooled Spare Mapping

In the schemes below, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

**Figure 1-34. NAND Page Mapping and ECC: Pooled Spare Schemes**

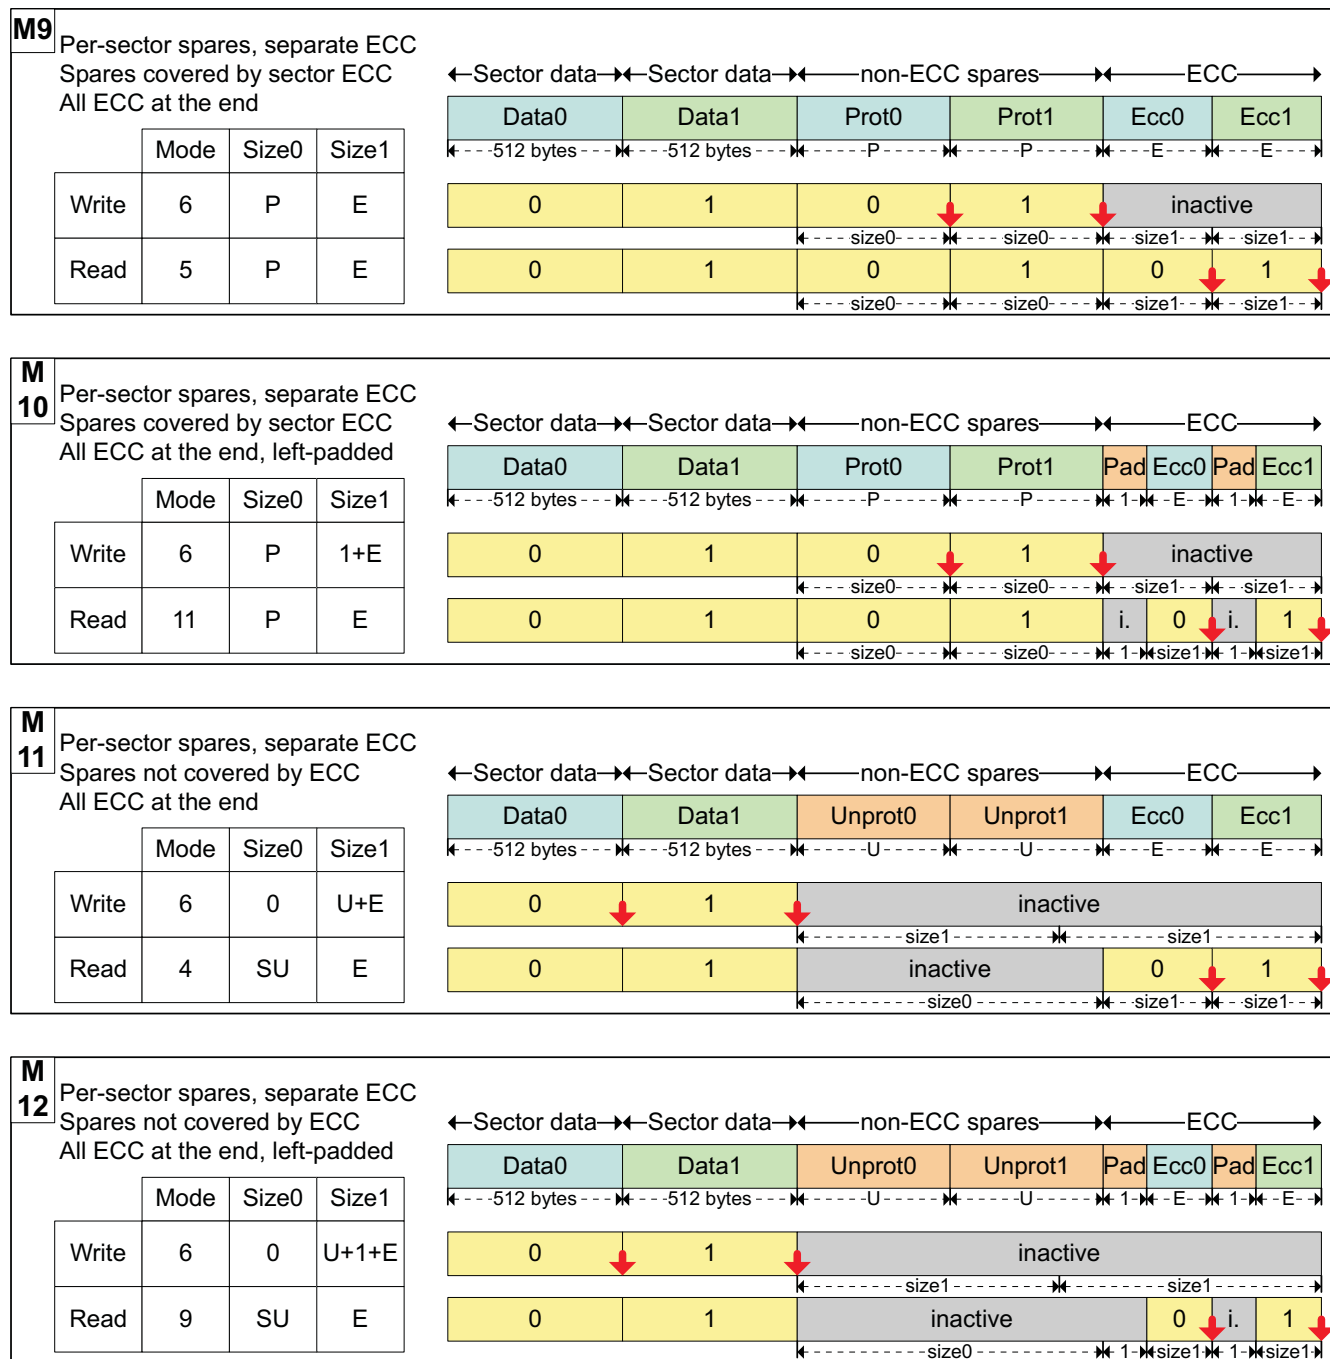

gpmc-034

#### 1.1.5.14.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with 2 sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

**Figure 1-35. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC**

gpmc\_035

#### 1.1.5.14.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MCU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine uses an embedded 64 bytes (32 Word16) FIFO to prefetch data

from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MCU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MCU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC.GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC.GPMC\_PREFETCH\_CONFIG1[19:16] PFPWWEIGHTEDPRIO field.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access). The engine does not include an address generator, and the request is limited to chip-select target identification. The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

---

**Note:** The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

---

#### 1.1.5.14.4.1 General Basic Programming Model

The engine can be configured only if the GPMC.GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC.GPMC\_PREFETCH\_CONFIG1[26:24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or Word16 access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of Word16.

When the GPMC.GPMC\_PREFETCH\_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the GPMC.GPMC\_NAND\_COMMAND\_i, GPMC.GPMC\_NAND\_ADDRESS\_i, and GPMC.GPMC\_NAND\_DATA\_i registers (where i = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with Byte, Word16, or Word32 access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC.GPMC\_PREFETCH\_STATUS[30:24] FIFOPointer field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC.GPMC\_PREFETCH\_STATUS[13:0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPointer and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPointer equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of Word32 or Word16 read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPointer equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

#### 1.1.5.14.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC.GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is cleared.

The MCU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC.GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (configured, reset, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC.GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the GPMC.GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 1.1.5.14.2.2](#). The GPMC.GPMC\_PREFETCH\_CONFIG1[5:4] WAITPINSELECTOR field selects which gpmc\_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to ensure that the FIFO is always filled with as much data as acceptable, until the programmed GPMC.GPMC\_PREFETCH\_CONFIG2[13:0] TRANSFERCOUNT field is completed.

**Table 1-15. Prefetch Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request

**Table 1-15. Prefetch Mode Configuration (continued)**

Bit Field	Register	Value	Comments
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 3	(If SynchroMode = 1) Selects wait pin edge detector
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 1.1.5.14.4.6</a> .
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 1.1.5.14.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC.GPMC\_PREFETCH\_STATUS[30:24] FIFOPINTER field or through the GPMC.GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC.GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC.GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC.GPMC\_PREFETCH\_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC.GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC.GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

**Note:** The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC.GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that

the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

#### 1.1.5.14.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC.GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is set.

The MCU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC.GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC.GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC.GPMC\_PREFETCH\_CONFIG2[13:0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

**Table 1-16. Write-Posting Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request

**Table 1-16. Write-Posting Mode Configuration (continued)**

Bit Field	Register	Value	Comments
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 1.1.5.14.4.6</a> .
CYCLOOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 1.1.5.14.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPINTER or through the GPMC.GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC.GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC.GPMC\_PREFETCH\_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC.GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

---

**Note:** The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

---

In DMA filling mode, the DMA Mode bit field in the GPMC.GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

#### 1.1.5.14.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC.GPMC\_NAND\_DATA\_i location,  $i = 0$  to 7) are never optimized.

The GPMC.GPMC\_PREFETCH\_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC.GPMC\_PREFETCH\_CONFIG1[30:28] CYCLEOPTIMIZATION field defines the number of GPMC\_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 1-36 highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by  $x$  clock cycles,  $x$  being defined by the GPMC\_PREFETCH\_CONFIG1[30:28] CYCLEOPTIMIZATION field.

**Figure 1-36. NAND Read Cycle Optimization Timing Description**

gpmc-036

#### 1.1.5.14.4.7 Interleaved Accesses between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC.GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC.GPMC\_PREFETCH\_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

## 1.1.6 GPMC Use Cases and Tips

### 1.1.6.1 How to Set GPMC Timing Parameters for Typical Accesses

#### 1.1.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Manufacturer: NOR Flash
- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

#### 1.1.6.1.2 Typical GPMC Setup

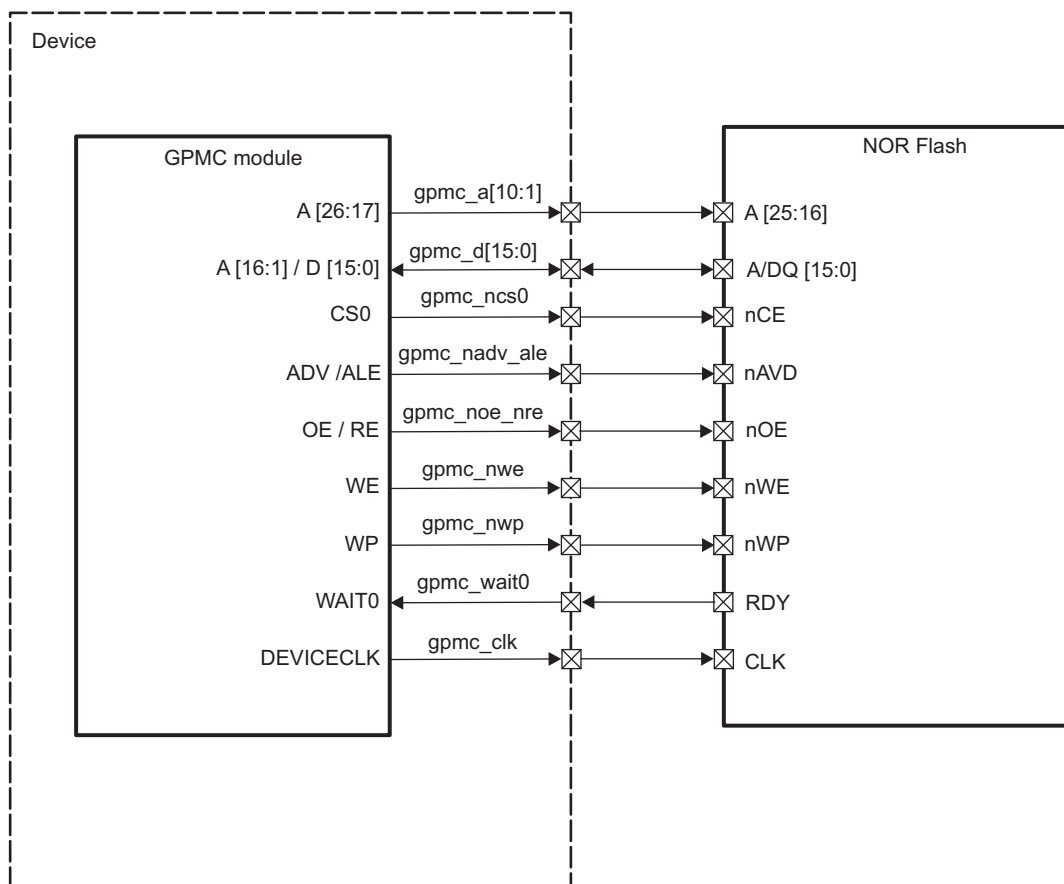

[Table 1-17](#) lists some of the I/Os of the GPMC module.

**Table 1-17. GPMC Signals**

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	I/O	External clock provided to the external device for synchronous operations
gpmc_a[10: 1]	O	Address
gpmc_d[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncs	O	Chip-select
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[3:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 1-37 shows the typical connection between the GPMC module and the attached NOR Flash memory.

**Figure 1-37. GPMC Connection to External NOR Flash Memory**

gpmc\_037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

#### 1.1.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9,615 \text{ ns}$ ).

Table 1-18 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 1-19 shows how to calculate timings for the GPMC using the memory parameters.

Figure 1-38 shows the synchronous burst read access.

**Table 1-18. Useful Timing Parameters on the Memory Side**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

**Table 1-18. Useful Timing Parameters on the Memory Side (continued)**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One burst of data is processed in one clock cycle ( $T = 9,615$  ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

**Table 1-19. Calculating GPMC Timing Parameters**

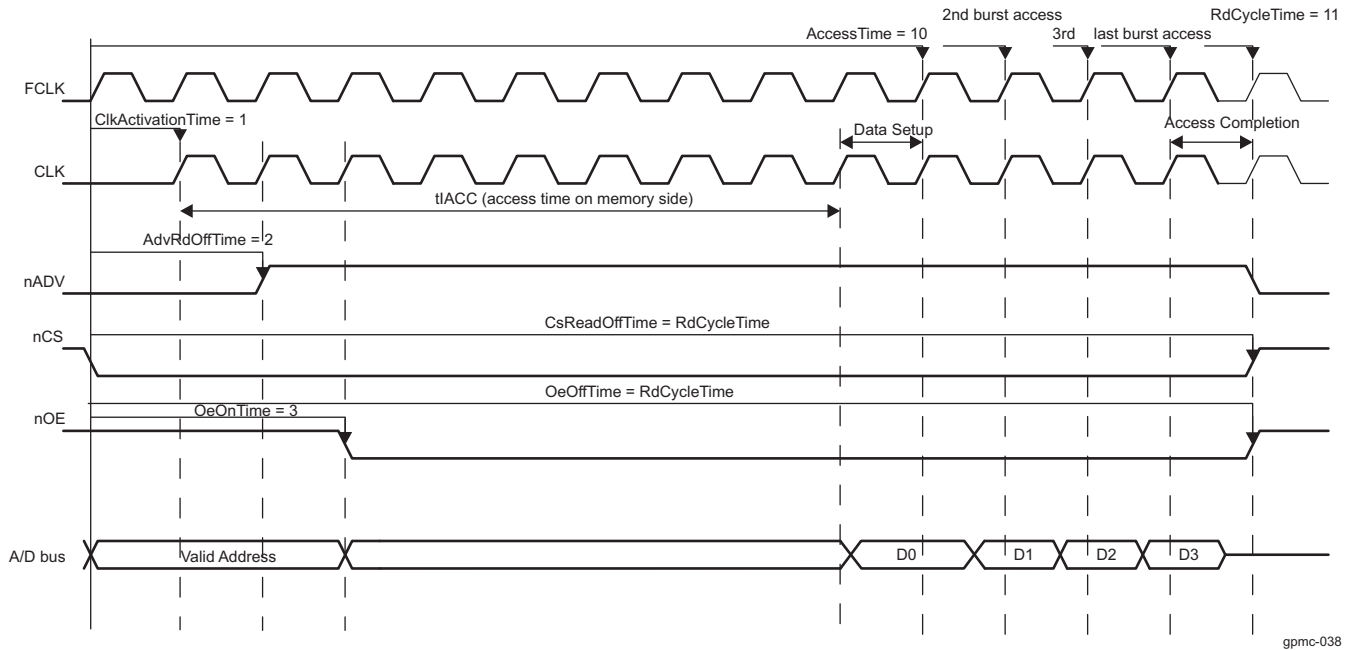

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	min ( tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94,03: (9,615 + 80 + 4,415)	10 : roundmax (94,03 / 9,615)	ACCESSTIME = 0x0A
PageBurstAccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	AccessTime + max ( tCEZ, tOEZ)	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC <sup>(1)</sup>	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC <sup>(2)</sup>	12	2	ADVRDOFFTIME = 0x02
OeOnTime <sup>(3)</sup>	(ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC)	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFFTIME = 0x0B

<sup>(1)</sup> The external clock provided to the NOR flash is not yet available.

<sup>(2)</sup> AdvRdOffTime - AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.

<sup>(3)</sup> OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

**Figure 1-38. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**

gpmc-038

#### 1.1.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9,615 \text{ ns}$ ).

Table 1-20 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 1-21 shows how to calculate timings for the GPMC using the memory parameters.

Figure 1-39 shows the asynchronous read access.

**Table 1-20. AC Characteristics for Asynchronous Read Access**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

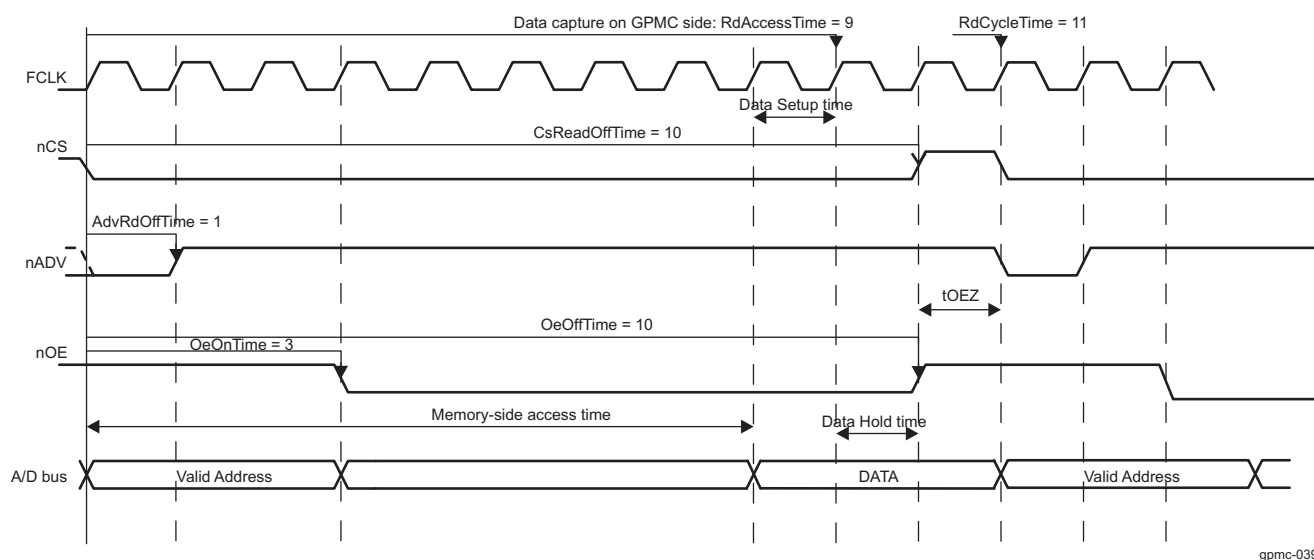

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 1-20: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus. The GPMC side requires some hold to allow the data to be captured correctly and the access to be finished.
- To read the data correctly, the GPMC must capture it with enough data setup time; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is 1 clock cycle ( $\text{AccessTime} + 1$ ).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

**Table 1-21. GPMC Timing Parameters for Asynchronous Read Access**

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	round max (tCE)	80	9	ACCESSTIME = 0x09
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	11	RDCYCLETIME = 0x0B
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	10	CSRDOFFTIME = 0x0A
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1cycle	89, 615	10	OEOFFTIME = 0x0A

**Figure 1-39. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)**

#### 1.1.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 1-23 shows how to calculate timings for the GPMC using the memory parameters.

Table 1-22 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 1-40 shows the synchronous burst write access.

**Table 1-22. AC Characteristics for Asynchronous Single Write ( Memory Side)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60

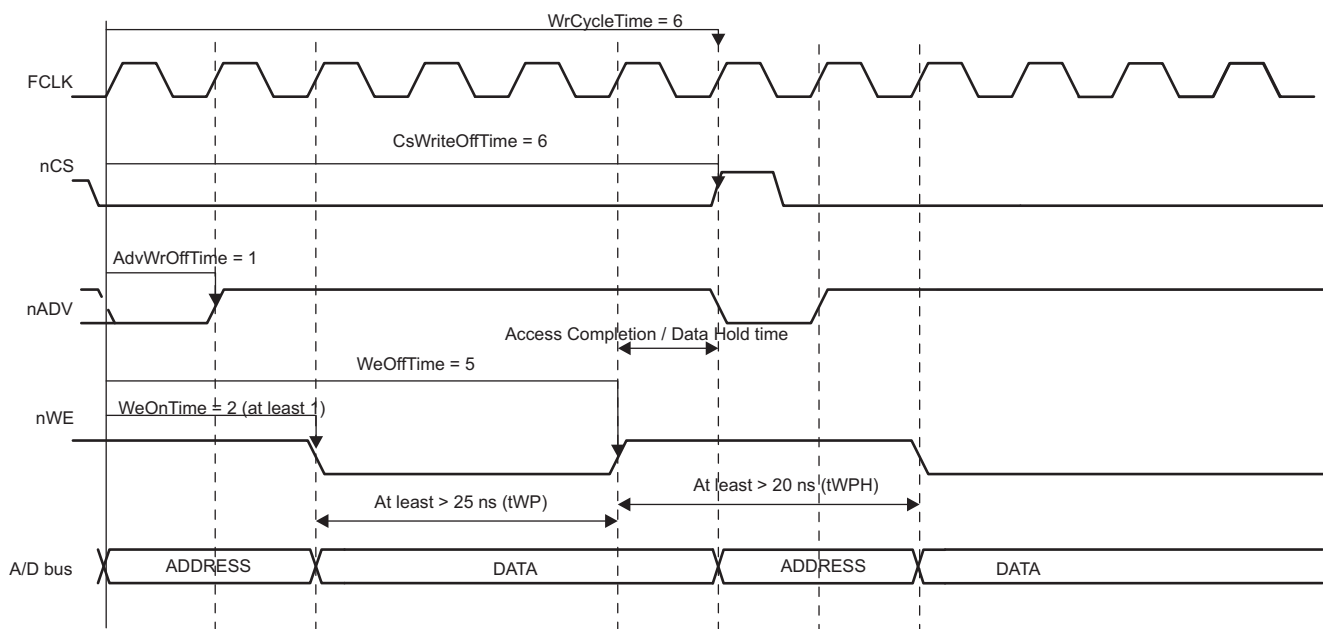

**Table 1-22. AC Characteristics for Asynchronous Single Write ( Memory Side) (continued)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is  $WrCycleTime = WeOffTime + AccessCompletion$  =  $WeOffTime + 1$ . For the AccessCompletion: 1 cycle is required for data hold time (nCS deassertion).

**Table 1-23. GPMC Timing Parameters for Asynchronous Single Write**

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		n/a (single access)		
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

**Figure 1-40. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)**

gpmc-040

### 1.1.6.2 How to Choose a Suitable Memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

#### 1.1.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

**Note:** Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

##### 1.1.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

**Table 1-24. Supported Memories Interfaces**

Function	16-bit Address/Data muxed pSRAM or NOR Flash <sup>(1)</sup>	OneNAND	16-bit NAND	8-bit NAND
gpmc_a10	A26			
gpmc_a9	A25

#### 1.1.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, i.e. read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 1-25 summarizes the NAND interface signals level applied to external device or memories.

**Table 1-25. NAND Interface Bus Operations Summary**

Bus operation	CLE	ALE	nCE	nWE <sup>(1)</sup>	nRE <sup>(1)</sup>	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H <sup>(2)</sup>	H <sup>(2)</sup>	H <sup>(2)</sup>	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L <sup>(3)</sup>

<sup>(1)</sup> RE stands for rising edge, FE stands for falling edge

<sup>(2)</sup> Can be either nCE high, or WE and nRE high.

<sup>(3)</sup> nWP should be biased to CMOS high or CMOS low for standby

### 1.1.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, i.e. is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 1-26 summarizes the NOR interface signals level applied to external device or memories.

**Table 1-26. NOR Interface Bus Operations Summary**

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

### 1.1.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

### 1.1.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to eight NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum operating frequency provided externally: up to 100MHz (single device) with an L3-clock of 100MHz. Up to 83MHz (L3-clock divided by two) with an L3-clock of 166MHz. See the device-specific Data Manual for precise information.
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 128 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

## 1.1.7 GPMC Registers

This section provides information about the GPMC instance in this product. [Table 1-28](#) provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

**Table 1-27. Instance Summary**

Module Name	Base Address	Size
GPMC	0x6E00 0000	16 Mbytes

### 1.1.7.1 GPMC Register Mapping Summary

**Table 1-28. GPMC Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address	Section
GPMC_SYSCONFIG	RW	32	0x0000 0010	0x6E00 0010	<a href="#">Section 1.1.7.2.1</a>

### 1.1.7.2 GPMC Register Descriptions

**Note:** All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC\_NAND\_DATA\_i register, are little endian. If the GPMC\_NAND\_DATA\_i register location is accessed, the endianness is access-dependent.

#### 1.1.7.2.1 GPMC\_SYSCONFIG

**Table 1-29. GPMC\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010

### 1.1.7.2.3 GPMC\_IRQSTATUS

**Table 1-31. GPMC\_IRQSTATUS**

<b>Address Offset</b>	0x0000 0018	<b>Instance</b>	GPMC
<b>Physical Address</b>	0x6E00 0018		
<b>Description</b>	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
RESERVED																WAIT3EDGEDETECTIONSTATUS				WAIT2EDGEDETECTIONSTATUS				WAIT1EDGEDETECTIONSTATUS				WAIT0EDGEDETECTIONSTATUS				RESERVED				TERMINALCOUNTSTATUS		FIFOEVENTSTATUS	

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
11	WAIT3EDGEDETECTIONSTATUS	Status of the Wait3 Edge Detection interrupt  Read 0x0: A transition on WAIT3 input pin has not been detected  Write 0x0: WAIT3EDGEDETECTIONSTATUS bit unchanged  Read 0x1: A transition on WAIT3 input pin has been detected  Write 0x1: WAIT3EDGEDETECTIONSTATUS bit is reset	RW	0x0

Bits	Field Name	Description	Type	Reset
10	WAIT2EDGEDETECTION STATUS	Status of the Wait2 Edge Detection interrupt Read 0x0: A transition on WAIT2 input pin has not been detected Write 0x0: WAIT2EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT2 input pin has been detected Write 0x1: WAIT2EDGEDETECTIONSTATUS bit is reset	RW	0x0
9	WAIT1EDGEDETECTION STATUS	Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected Write 0x0: WAIT1EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT1 input pin has been detected Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset	RW	0x0
8	WAIT0EDGEDETECTION STATUS	Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected Write 0x0: WAIT0EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT0 input pin has been detected Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTSTATUS	Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit unchanged Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset	RW	0x0
0	FIFOEVENTSTATUS	Status of the FIFOEvent interrupt Read 0x0: Indicates than less than FIFOThreshold bytes are available in prefetch mode and less than FIFOThreshold bytes free places are available in write-posting mode. Write 0x0: FIFOEVENTSTATUS bit unchanged Read 0x1: Indicates than at least FIFOThreshold bytes are available in prefetch mode and at least FIFOThreshold bytes free places are available in write-posting mode. Write 0x1: FIFOEVENTSTATUS bit is reset	RW	0x0

### 1.1.7.2.5 GPMC\_TIMEOUT\_CONTROL

**Table 1-33. GPMC\_TIMEOUT\_CONTROL**

<b>Address Offset</b>	0x0000 0040																															
<b>Physical Address</b>	0x6E00 0040															<b>Instance</b>	GPMC															
<b>Description</b>	The GPMC_TIMEOUT_CONTROL register allows the user to set the start value of the timeout counter																															
<b>Type</b>	RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED																		TIMEOUTSTARTVALUE								RESERVED		TIMEOUTENABLE				
<b>Bits</b>	<b>Field Name</b>		<b>Description</b>													<b>Type</b>		<b>Reset</b>														
31:13	RESERVED		Write 0s for future compatibility. Read returns 0s.													RW		0x00000														
12:4	TIMEOUTSTARTVALUE		Start value of the time-out counter 0x000: Zero GPMC_FCLK cycle 0x001: One GPMC_FCLK cycle ... 0x1FF: 511 GPMC_FCLK cycles													RW		0x1FF														
3:1	RESERVED		Write 0s for future compatibility. Read returns 0s.													RW		0x0														
0	TIMEOUTENABLE		Enable bit of the TimeOut feature 0x0: TimeOut feature is disabled 0x1: TimeOut feature is enabled													RW		0x0														

### 1.1.7.2.6 GPMC\_ERR\_ADDRESS

**Table 1-34. GPMC\_ERR\_ADDRESS**

<b>Address Offset</b>		0x0000 0044																																																															
<b>Physical Address</b>		0x6E00 0044																<b>Instance</b>																GPMC																															
<b>Description</b>		The GPMC_ERR_ADDRESS register stores the address of the illegal access when an error occurs																																																															
<b>Type</b>		RW																																																															
RESERVED		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																																
		ILLEGALADD																																																															
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>																																<b>Type</b>																<b>Reset</b>															
31	RESERVED	Write 0s for future compatibility. Read returns 0.																																RW																0x0															
30:0	ILLEGALADD	Address of illegal access A30: 0 for memory region, 1 for GPMC register region A29-A0: 1 GBytes max																																R																0x00000000															

### 1.1.7.2.7 GPMC\_ERR\_TYPE

**Table 1-35. GPMC\_ERR\_TYPE**

Address Offset		0x0000 0048																Instance		GPMC											
Physical Address		0x6E00 0048																													
Description		The GPMC_ERR_TYPE register stores the type of error when an error occurs																													
Type		RW																													

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10:8	ILLEGALMCMD	System Command of the transaction that caused the error	R	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	ERRORNOTSUPPADD	Not supported Address error 0x0: No error occurs 0x1: The error is due to a non supported Address	R	0x0
3	ERRORNOTSUPPMCMD	Not supported Command error 0x0: No error occurs 0x1: The error is due to a non supported Command	R	0x0
2	ERRORTIMEOUT	Time-out error 0x0: No error occurs 0x1: The error is due to a time out	R	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	ERRORVALID	Error validity status - Must be explicitly cleared with a write 1 transaction 0x0: All error fields no longer valid 0x1: Error detected and logged in the other error fields	RW	0x0

### 1.1.7.2.8 GPMC\_CONFIG

**Table 1-36. GPMC\_CONFIG**

<b>Address Offset</b>	0x0000 0050	<b>Instance</b>	GPMC
<b>Physical Address</b>	0x6E00 0050		
<b>Description</b>	The configuration register allows global configuration of the GPMC		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WAIT3PINPOLARITY				WAIT2PINPOLARITY				WAIT1PINPOLARITY				WAIT0PINPOLARITY			
																RESERVED				WRITEPROTECT				RESERVED				LIMITEDADDRESS		NANDFORCEPOSTEDWRITE	

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3PINPOLARITY	Selects the polarity of input pin WAIT3 0x0: WAIT3 active low 0x1: WAIT3 active high	RW	0x1
10	WAIT2PINPOLARITY	Selects the polarity of input pin WAIT2 0x0: WAIT2 active low 0x1: WAIT2 active high	RW	0x0
9	WAIT1PINPOLARITY	Selects the polarity of input pin WAIT1 0x0: WAIT1 active low 0x1: WAIT1 active high	RW	0x1
8	WAIT0PINPOLARITY	Selects the polarity of input pin WAIT0 0x0: WAIT0 active low 0x1: WAIT0 active high	RW	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	WRITEPROTECT	Controls the WP output pin level 0x0: WP output pin is low 0x1: WP output pin is high	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1	LIMITEDADDRESS	Limited Address device support 0x0: No effect 0x1: A26-A11 are not modified during an external memory access.	RW	0x0
0	NANDFORCEPOSTEDWRITE	Enables the Force Posted Write feature to NAND Cmd/Add/Data location 0x0: Disables Force Posted Write 0x1: Enables Force Posted Write	RW	0x0

### 1.1.7.2.9 GPMC\_STATUS

**Table 1-37. GPMC\_STATUS**

Address Offset		0x0000 0054																Instance		GPMC									
Physical Address		0x6E00 0054																											
Description		The status register provides global status bits of the GPMC																											
Type		RW																											

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
RESERVED																WAIT3STATUS				WAIT2STATUS				WAIT1STATUS				WAIT0STATUS				RESERVED				EMPTYWRITEBUFFERSTATUS	

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3STATUS	Is a copy of input pin WAIT3. (Reset value is WAIT3 input pin sampled at IC reset) 0x0: WAIT3 asserted (inactive state) 0x1: WAIT3 de-asserted	R	0x-
10	WAIT2STATUS	Is a copy of input pin WAIT2. (Reset value is WAIT2 input pin sampled at IC reset) 0x0: WAIT2 asserted (inactive state) 0x1: WAIT2 de-asserted	R	0x-
9	WAIT1STATUS	Is a copy of input pin WAIT1. (Reset value is WAIT1 input pin sampled at IC reset) 0x0: WAIT1 asserted (inactive state) 0x1: WAIT1 de-asserted	R	0x-
8	WAIT0STATUS	Is a copy of input pin WAIT0. (Reset value is WAIT0 input pin sampled at IC reset) 0x0: WAIT0 asserted (inactive state) 0x1: WAIT0 de-asserted	R	0x-
7:1	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x00
0	EMPTYWRITEBUFFERSTATUS	Stores the empty status of the write buffer 0x0: Write Buffer is not empty 0x1: Write Buffer is empty	R	0x1

### 1.1.7.2.10 GPMC\_CONFIG1\_i

**Table 1-38. GPMC\_CONFIG1\_i**

<b>Address Offset</b>	0x0000 0060 + (0x0000 0030 * I)	<b>Index</b>	I = 0 to 7
<b>Physical Address</b>	0x6E00 0060 + (0x0000 0030 * I)	<b>Instance</b>	GPMC
<b>Description</b>	The configuration register 1 sets signal control parameters per chip-select		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 1.2 SDRAM Controller (SDRC) Subsystem

This section describes the SDRAM controller (SDRC) subsystem of the OMAP35x Applications Processor.

### 1.2.1 SDRC Subsystem Overview

---

**Note:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

---

The SDRC subsystem module provides connectivity between the OMAP Applications Processor and external discrete or POP-ed low-power double-data-rate SDRAM (LPDDR).

The SDRC subsystem provides a high-performance interface to a variety of fast memory devices. It comprises two submodules:

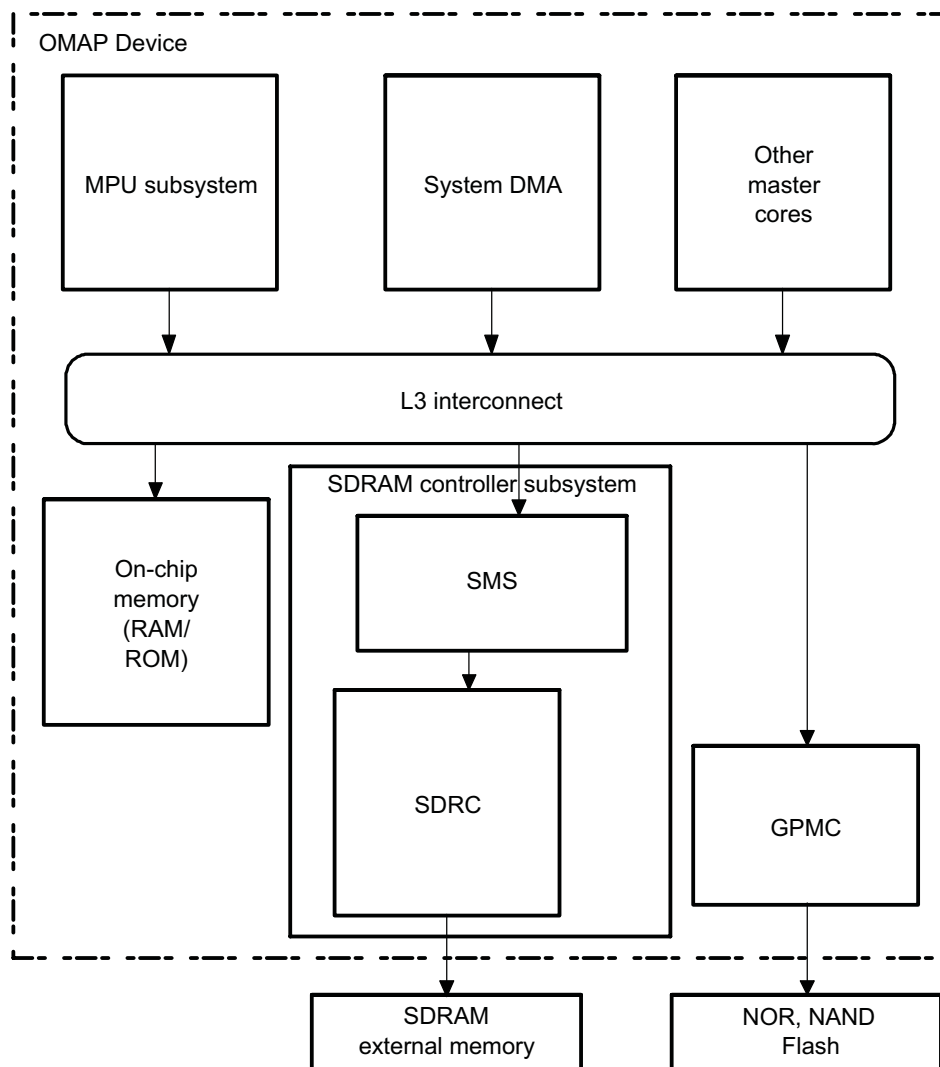

- The SDRAM Memory Scheduler (SMS), consisting of scheduler, security firewall, and virtual rotated frame-buffer (VRFB) modules.
- The SDRC.

[Figure 1-41](#) shows the SDRC subsystem environment.

---

**Note:** For DDR connectivity, refer to the device specific data manual.

---

**Figure 1-41. SDRC Subsystem Environment**

sdrc-001

### 1.2.1.1 Features

The main features of the SDRC subsystem module are:

- Security firewall
  - Eight regions can be defined.
  - Independently programmable read/write access control
  - Independently programmable security control
- VRFB module
  - Minimizes SDRAM page-miss penalty when accessing graphics buffer in nonnatural raster-scan order
  - Supports rotations of 0, 90, 180, and 270 degrees
  - Transparent to software applications
  - 12 concurrent rotation contexts
- Memory-access scheduler
  - Optimizes latency and bandwidth usage between initiators
  - Supports secure transactions controlled by security firewall

- Per-system initiator group quality-of-service (QoS) control
- $8 \times 8 \times 64$  request queue FIFO for optimal scheduling
- Programmable arbitration scheme
- Focus on real-time memory processes (LCD display, camera interface)
- Focus on MPU/DSP memory latency
- Fair arbitration between other system initiators (DMAs, video subsystem, SGX accelerator)
- Exclusive read-write transaction support
- Region-based security firewall in accordance with OMAP Applications Processor security management
- SDRAM Controller
  - Support for two independent CSs, with their corresponding register sets, and independent page tracking
  - Supports the following memory type:
    - Low-Power Double Data Rate SDRAM (LPDDR)
  - Memory device capacity:
    - 16 Mbits, 32 Mbits, 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, and 2 Gbits device support
  - Memory device organization
    - 2-bank support for 16 Mbits and 32 Mbits
    - 4-bank support for 64 Mbits to 2 Gbits
    - Flexible row/column address multiplexing schemes
    - Bank linear addressing
    - 16- or 32-bit data path to external SDRAM memory
    - 1 Gbyte maximum addressing capability
    - Device driver strength feature for mobile DDR supported
    - New flexible address-muxing scheme lets users choose different bank mapping allocations by configuring the bank and column address decoding ordering.
  - Fully pipelined operation for optimal memory bandwidth usage
  - Burst support
    - Memory burst support
      - System burst for mobile DDR SDRAM: system burst translated into memory burst size of 4
      - Read interrupt by read, write interrupt by write
  - CAS latency support 1, 2, 3, 4, 5
  - Fully programmable ac timing parameters (on a per-parameter basis). Parameters are set according to the memory interface clock frequency with respect to the attached memory device timing specifications.
  - Fine tuning of the controlled delay elements when operating with DDR memory
  - Dynamic endianness support
  - $9 \times 64$  bit look-ahead FIFO in the SDRAM controller with a maximum of four transaction entries
  - Low-power management support
    - Dynamic power-saving features (internal clock gating)
    - Static power-saving features
    - Support for all standard low-power memory features
    - Support for enhanced low-power features (mobile devices)
    - Very low-power controlled-delay technology for optimal performance with DDR memory
    - Can operate with mobile DDR memory at very low clock rates
  - Autorefresh and self-refresh management

---

**Note:** The OMAP Applications Processor does not support regular DDR devices due to electrical incompatibility.

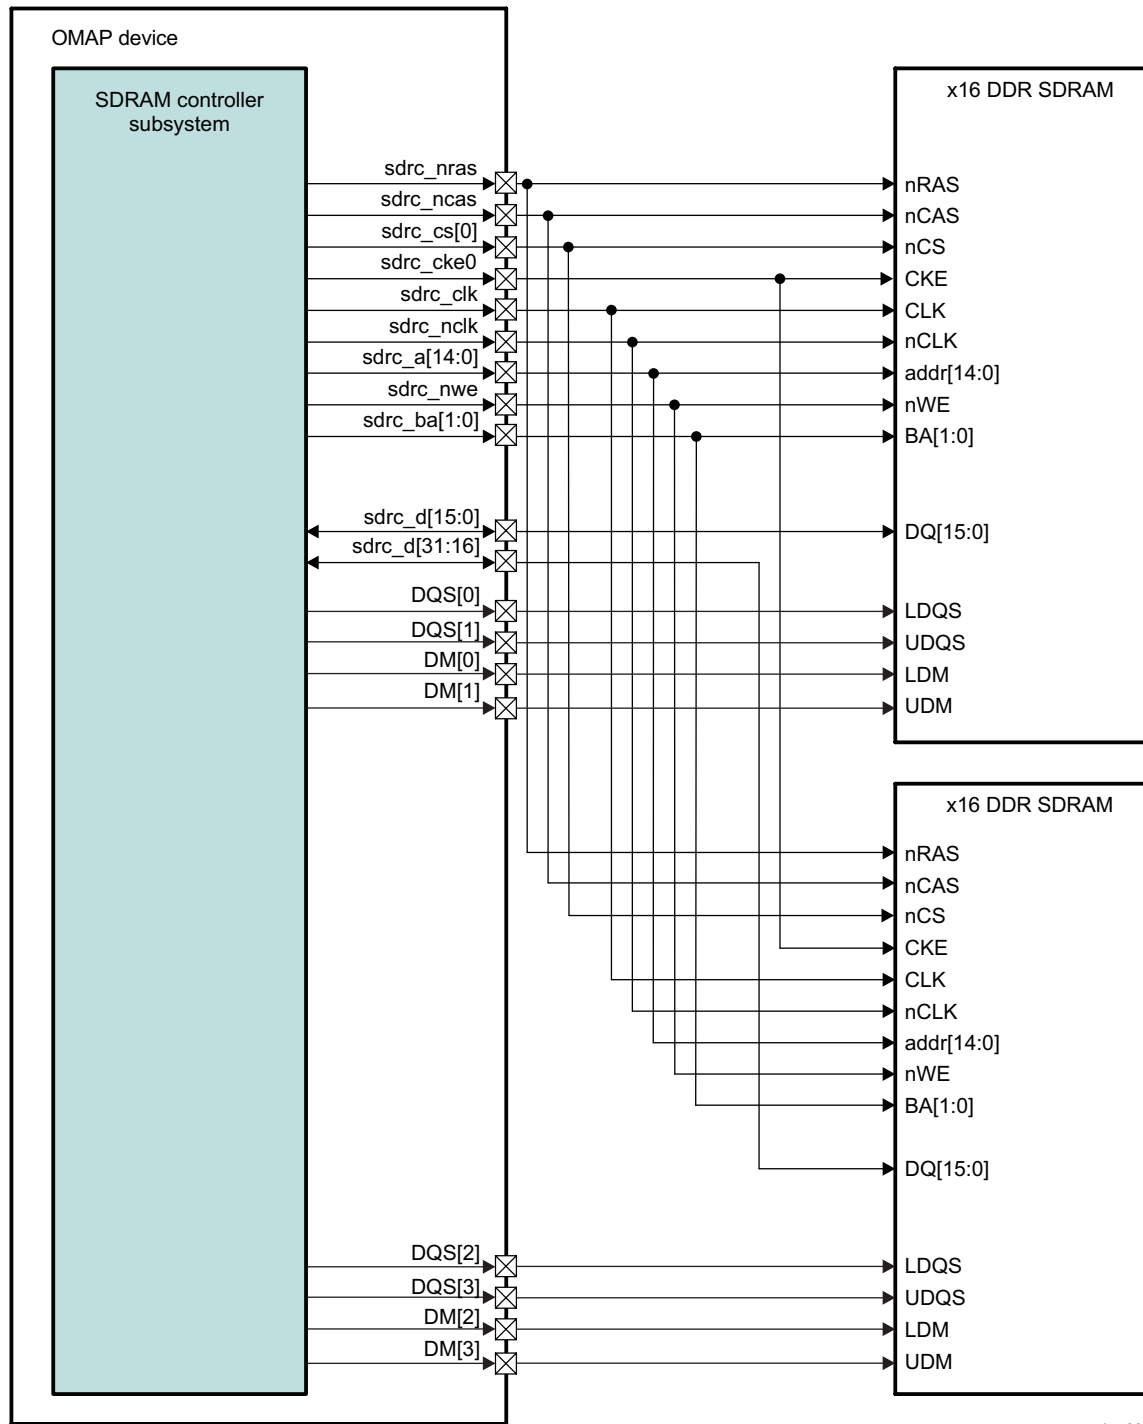

---

## 1.2.2 SDRC Subsystem Environment

### 1.2.2.1 SDRC Subsystem Description

Figure 1-42 shows the SDRC subsystem interfacing with two 16-bit DDR memories.

Figure 1-42. SDRC Subsystem Connections to DDR SDRAM

**Note:** For DDR connectivity, refer to the device specific data manual.

Table 1-61 lists SDRC subsystem I/O pins.

**Table 1-61. SDRC Subsystem I/O Description**

Pin	Type	Description
sdrc_d[31:0]	I/O	32-bit wide data bus
sdrc_ba[1:0]	O	Bank address 1-0
sdrc_a[14:0]	O	Address bus
sdrc_ncs[1:0]	O	Chip-select 1-0 (active low)
sdrc_clk	O	Clock <sup>(1)</sup>
sdrc_nclk	O	Clock invert
sdrc_cke0	O	Clock enable (CS0)
sdrc_cke1	O	Clock enable (CS1)
sdrc_nras	O	Row address strobe (active low)
sdrc_ncas	O	Column address strobe (active low)
sdrc_nwe	O	Write enable (active low)
sdrc_dm[3:0]	O	Data mask
sdrc_dqs[3:0]	I/O	Data output strobe

<sup>(1)</sup> This output signal is also used as re-timing input.

## 1.2.2.2 External Interface Configuration

### 1.2.2.2.1 CS0, CS1 Memory Spaces

The SDRC can be connected independently to two external SDRAM memories.

---

**Note:** For DDR connectivity, refer to the device specific data manual.

---

SDRAM memory is supported in sizes of 16 Mbits, 32 Mbits, 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, and 2 Gbits. See [Section 1.2.4.4.1](#) for more information on CS memory spaces.

---

**Note:** The OMAP Applications Processor does not support regular DDR devices (see [Section 1.2.5.3.5.1, Chip-Select Configuration](#)).

---

### 1.2.2.2.2 AC Timing Control

The SDRC permits the configuration of many of the ac timing parameters controlling the SDRAM transaction timing.

It is required to adapt the transaction timing parameters to any memory device attached to the SDRC.

---

**Note:** See the OMAP device-specific data manual for optimum results.

---

A totally independent, complete set of parameters exists for each CS. The ac parameters and their quantification are summarized in [Section 1.2.5.3.1, Chip-Select Configuration](#).

### 1.2.2.2.3 Address Multiplexing

A flexible address scheme has been added to support any new type of address scheme and SDRAM density. This new address-muxing scheme lets users choose a different bank mapping allocation by configuring the order of the bank and row address decoding (column address always remains the same). The SDRC.SDRC\_MCFG\_p[7:6] BANKALLOCATION field defines the order of the bank and row decoding of the incoming system address. The BANKALLOCATION field can be set on a CS basis. For more details about the flexible address scheme, see [Section 1.2.4.4.3, Address Multiplexing](#).

The programming model is compatible with the legacy fixed address scheme and with the new flexible address scheme. This section describes the fixed address multiplexing configurations for both SDRAM components.

The legacy fixed address scheme is selected when the SDRC.SDRC\_MCFG\_p[19] ADDRMUXLEGACY bit is set to 0 (where p = 0 or 1 for SDRC CS0 or CS1). The fixed address multiplexing configurations are described in this section, for both SDRAM components. An address multiplexing scheme is chosen by programming the SDRC.SDRC\_MCFG\_p[24:20] ADDRMUX field of the SDRC\_MEMCFG registers on a per chip select basis (p = 0 or 1 for CS0 or CS1). [Table 1-62](#) and [Table 1-63](#) show all pre-defined address multiplexing schemes for SDRAM memory components.

**Table 1-62. SDRC Address Multiplexing Scheme Selection vs SDRAM Configurations (x16 Memory Interface)**

x16 Memory Interface								
Banks		Column Address		Row Address	MUX Scheme	Total Size (Mbits)	Number of Devices	Device Organization

**Table 1-63. SDRC Address Multiplexing Scheme Selection vs SDRAM Configurations (x32 Memory Interface) (continued)**

x32 Memory Interface									
Banks		Column Address		Row Address		MUX Scheme	Total Size (MBits)	Number of Devices	Device Organization
BA1, BA0	2	A0-A9	10	A0-A12	13	MUX14	1024	1	16M x 32
								4	32M x 8
								2	32M x 16
								1	32M x 32
BA1, BA0	2	A0-A9	10	A0-A13	14	MUX16	2048	2	64M x 16
								1	64M x 32
BA1, BA0	2	A0-A9	10	A0-A14	15	MUX29	4096	1	128M x 32
BA1, BA0	2	A0-A9; A11	11	A0-A12	13	MUX15	2048	4	64M x 8
								2	64M x 16
								1	64M x 32

Table 1-62 is valid per CS (in the table, the total size in Mbits corresponds to a single CS). Both chips must use the same address scheme, but can use different address multiplexing configurations.

Figure 1-43 through Figure 1-45 show all the SDRAM MUX schemes, including the mapping of the 32-bit system address of the column and row addresses of the memory device.

---

**Note:** The bank-select bit (BA1) does not exist for 2-bank devices.

### 1.2.3 SDRC Subsystem Integration

Figure 1-46 shows how the SMS and SDRC modules are integrated into the OMAP Applications Processor and how they interact with the PRCM module.

**Figure 1-46. SDRC Integration to the OMAP Applications Processor**

### 1.2.3.1 Clocking, Reset, and Power Management Scheme

#### 1.2.3.1.1 Clocking

##### 1.2.3.1.1.1 SMS

The SMS is a single clock domain module. The same clock is used for the interconnect system interface, the SDRC interface, and all internal operations.

SMS\_CLK comes internally from the PRCM module and runs at the L3 interconnect frequency. It is also used as a functional clock for the SMS module.

The source of the SMS\_CLK is the PRCM CORE\_L3\_ICLK output: CORE\_L3\_ICLK belongs to the L3 interconnect clock domain.

##### 1.2.3.1.1.2 SDRC

The SDRC is a single-clock domain module. The same clock is used for both the interconnect and the memory interface. The SDRC\_CLK clock comes from the PRCM and runs at the L3 interconnect frequency. SDRC\_CLK is also used as a functional clock for the SDRC.

The SDRC\_CLK clock source is the PRCM CORE\_L3\_ICLK output: CORE\_L3\_ICLK belongs to the L3 interconnect clock domain.

An SDRC\_CLKX2 clock is provided by the PRCM at a double frequency of the SDRC\_CLK clock. This clock can be used in the LPDDR write path, depending on the configuration.

As a power-saving feature, when the SDRC no longer requires the clock domain, the software can disable it at the PRCM level by setting the EN\_SDRC bit in the PRCM.CM\_ICKLEN1\_CORE[1] register.

---

**Note:** The domain clock is shut down only if all other modules that receive the clock are capable and ready to accept this idle request and have IdleAck asserted.

---

For details, see the *Power, Reset, and Clock Management* chapter.

#### 1.2.3.1.2 Hardware Reset

Global reset of the SDRC is done by activating the CORE\_RST signal in the CORE\_RST domain (see the *Power, Reset, and Clock Management* chapter).

There is one global reset signal, SDRC\_GLOBALRESET, which is qualified by the signal SDRC\_POWERON. This qualification differentiates whether the signal is a cold reset or a warm reset.

- On a cold reset (that is, the power-on reset, when SDRC\_POWERON = 0 and SDRC\_GLOBALRESET is applied), all registers and state-machines within the SDRC are asynchronously reset.
- On a warm reset (that is, any other system reset condition under control of the chip top-level power manager, SDRC\_POWERON = 1 when SDRC\_GLOBALRESET is applied), the SDRC registers and the FSM are not reset, but the external SDRAM memory can be optionally placed in self-refresh mode, depending on the configuration of the SDRC.SDRC\_POWER\_REG[7] SRFONRESET bit.

#### 1.2.3.1.3 Software Reset

The SMS and SDRC modules can be reset under software control through the SMS.SMS\_SYSCONFIG[1] SOFTRESET and SDRC.SDRC\_SYSCONFIG[1] SOFTRESET bits, respectively.

A software reset has the same action as a hardware cold reset, that is, the FSM and all registers are reset immediately and unconditionally.

#### 1.2.3.1.4 Power Management

The SDRC power is supplied by the CORE power domain. For details, see the *Power, Reset, and Clock Management* chapter.

The dynamic voltage and frequency scaling (DVFS) technic is described in the following section while other power-saving features and different idle modes are described in [Section 1.2.4.4, SDRC](#).

##### 1.2.3.1.4.1 Dynamic Voltage and Frequency Scaling

If the input clock SDRC\_CLK from the PRCM module is changed during operations, the DLL may enter an undefined state and memory accesses may be corrupted. For this reason, it is necessary to manually assert the SDRC\_IDLREQ signal before any clock frequency change. This manual access is done through a register in the chip clock controller. The SDRC then finishes processing all open transactions. If this option is activated in the SDRC\_POWER\_REG[6] SRFRONIDLREQ bit, it puts the memory into self-refresh. When done, it unlocks the DLL and puts it into a power-down state through the SDRC.SDRC\_DLLA\_CTRL[6:5] DLLMODEONIDLREQ field. The SDRC then asserts the SDRC\_SIDLEACK signal and the input clock frequency can be changed or stopped, depending on the scenario. After the input clock is stable again, SDRC\_IDLREQ is de-asserted. The DLL then relocks and the SDRC can be accessed normally. Putting the DLL in idle mode during the clock frequency change is required because it cannot automatically relock. It might get into a non-functional state and a new manual DLL configuration phase would then be required, with the risk of corrupting accesses in the mean time.

## 1.2.4 SDRC Subsystem Functional Description

The SMS optimizes the SDRAM memory usage to provide:

- The QoS level required by each of the initiators in the system
- A security firewall that controls access protection to the memory
- A VRFB module (also called the 2D rotation engine) that minimizes the SDRAM page-miss penalty when accessing rotated (that is, nonsequentially addressed) lines in a graphic frame buffer

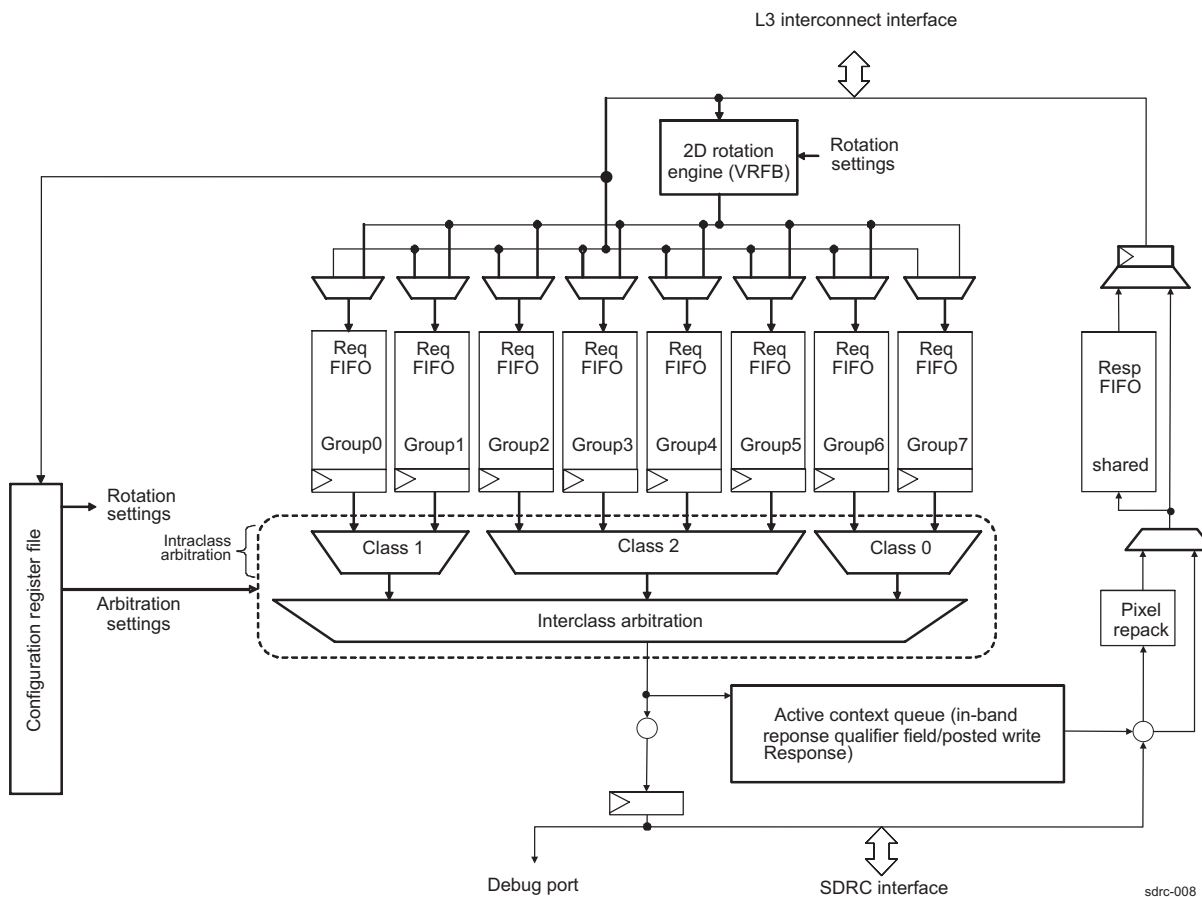

### 1.2.4.1 SDRAM Memory Scheduler

The SMS module is split into the following subsystems:

- L3 interconnect slave port
- VRFB: rotation engine (RE)
- Configuration register file
- Security check unit
- Request buffers
- Arbitration logic
- SDRC interface: master port
- Debug port
- Response buffer

Figure 1-47 shows the top-level diagram of the SMS.

Figure 1-47. SMS Top-Level Diagram

### 1.2.4.1.1 Memory Access Scheduling

**Note:** For a description of the SMS mode of operation and arbitration policy, see [Section 1.2.6, SDRC Use Cases and Tips](#).

The SMS includes a set of FIFOs to queue the requests received from the system interconnect or processed by the RE. The FIFO entry contains a complete interconnect request, plus internal qualifiers added by the RE which are required to correctly process the requests modified (or generated) by the RE.

The SMS also includes a response FIFO, which is shared by all response threads. This FIFO provides full support for the response flow-control interconnect extension (handshake protocol).

When a memory transaction request arrives in the memory-access scheduler after being processed by the VRFB module, the request is sent to one of eight FIFO queues. Security firewall comes after the FIFOs.

The allocation to a particular queue is fixed and depends on the source of the request. To prioritize concurrent transactions and optimize memory usage, each FIFO queue (and hence the memory-access request source) is categorized into one of these three arbitration classes:

- **Class 0 (highest priority):** For bandwidth-sensitive devices with severe real-time constraints. The system fails when the bandwidth requirement is not met. LCD or video display cores, camera capture cores belong to this category.
- **Class 1:** For latency-sensitive devices where system performance degrades severely when the average memory-access latency increases. These initiators also generally have some significant bandwidth requirements. All CPU cores are class 1 initiators.
- **Class 2:** For all other devices, possibly with high-bandwidth requirements but without being too latency-sensitive. Associated initiators may also have significant requirements in terms of bandwidth, but if the bandwidth budget requirement cannot be serviced, the system performance degrades, but remains functional (the system does not fail). General-purpose system DMA, multimedia accelerators (graphics, imaging, video) belong to this category.

The arbitration between Class 1 and Class 2 is programmable.

[Table 1-64](#) shows the mapping of FIFO queues and memory-access request sources to arbitration classes.

**Table 1-64. Arbitration Class Allocation**

Class	FIFO Queue	Source Device
0	6	D2D
	7	Display and Camera subsystems
1	0	MPU subsystem (instruction and data access)
	1	IVA2 subsystem (instruction, data access, and MMU)
2	2	IVA2 subsystem DMA (read and write), sDMA WR
	3	SGX
	4	USB (HS + FS), DAP
	5	sDMA (read)

A 2-level arbitration scheme determines the FIFO queue from which the next memory transaction is granted.

**Note:** In the register description, a group represents a FIFO queue of requests from the initiator.

### 1.2.4.1.2 Arbitration Policy

A 2-level arbitration scheme is implemented to grant access to the SDRC. The arbitration uses fully combinatorial logic, and the granted request is clocked before being issued on the interface master port of the SDRC.

- Intra-class arbitration: A first level of arbitration is done in parallel within each class between the different thread groups (request FIFOs).
- Interclass arbitration: A second level of arbitration is done among the three winners of the in-class arbitration.

#### 1.2.4.1.2.1 Arbitration Policy within a Burst and at a Burst Boundary

Arbitration is performed on the transaction boundary. The transaction can be either a single transaction or a burst transaction.

- Within a burst, if the thread cannot provide the subsequent request of the burst, a mechanism provides a wait for one idle cycle before moving the arbitration grant to the next thread. If only one idle cycle appears on one thread, an arbitration grant must not move (the next request served must be from the same thread). One idle cycle is then inserted in the SDRC request path.
- If the thread still cannot provide the request in the next cycle, the slot can be awarded to another initiator to avoid locking the SDRAM resource, if a thread cannot supply a subsequent request within the burst. In this case, there must not be a second idle cycle insertion in the SDRC request path. A burst with fewer than two idle cycles cannot be interrupted by a higher priority request.
- On burst boundary, the arbitration does not wait one idle cycle before moving the arbitration grant. As soon as the thread cannot request one transaction at a burst boundary, the arbitration grant can move to the next thread.

This is also valid within the ExtendedGrant and NOFServices windows; as soon as the thread cannot request a transaction, the arbitration grant can move to the next thread. For more information, see the following descriptions of the ExtendedGrant and NOFServices features.

#### 1.2.4.1.2.2 Burst-Complete Feature (BURST-COMPLETE Field in SMS\_CLASS\_ARBITER0, SMS\_CLASS\_ARBITER1, SMS\_CLASS\_ARBITER2)

A burst request can be submitted to the arbitration either as soon as the first request of the burst is received by the SMS, or when at least one complete burst is buffered into the FIFO. The behavior is programmable on a per-group basis using the BURST-COMPLETE field of the SMS\_CLASS\_ARBITER0, SMS\_CLASS\_ARBITER1, and SMS\_CLASS\_ARBITER2 registers. A per-FIFO counter tracks the number of complete bursts in a FIFO.

#### 1.2.4.1.2.3 ExtendedGrant Feature (EXTENDEDGRANT Field in SMS\_CLASS\_ARBITER0, SMS\_CLASS\_ARBITER1, SMS\_CLASS\_ARBITER2)

EXTENDEDGRANT is a programmable control field that allows a group to be granted for N consecutive transactions (single or burst), assuming the group is still requesting service (FIFO is not empty). EXTENDEDGRANT is applicable on a single/burst boundary. This multiple-service grant is intended to take advantage of the high probability of two consecutive transactions within a group accessing consecutive memory addresses (that is, in the same SDRAM page). This mechanism does not apply to consecutive transactions that have been split by the RE. The maximum number of consecutive grants is given in the EXTENDEDGRANT field of the SMS\_CLASS\_ARBITER0, SMS\_CLASS\_ARBITER1, and SMS\_CLASS\_ARBITER2 registers. The allowed range is 1 to 3.

The ExtendedGrant logic is in the internal class arbitration but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the ExtendedGrant scheme of class 1/class 2. Within an ExtendedGrant window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary.
- The PWM counter of the interclass arbitration obeys the ExtendedGrant completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the ExtendedGrant window starts with the last ExtendedGrant counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOFServices. The ExtendedGrant counter is reloaded to its programmed value when it reaches 0.

#### 1.2.4.1.2.4 NOFServices Feature (SMS.SMS\_CLASS\_ROTATIONm[4:0] NOFSERVICES Field)

NOFSERVICES is a programmable control field that allows consecutive transactions (single or burst) coming from the VRFB (with an RE\_split qualifier) to be granted consecutively, assuming the group is still requesting service (FIFO is not empty). NOFServices is applicable to the RE single/burst boundary. The maximum number of consecutive grants is given by the NOFSERVICES field of the SMS.SMS\_CLASS\_ROTATIONm registers. The allowable range is 1 to 31.

The NOFServices logic is in the internal class arbitration, but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the NOFServices scheme of class 1/class 2. Within a NOFService window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary. A burst with fewer than two idle cycles cannot be interrupted by a class 0 request.
- The PWM counter of the interclass arbitration obeys the NOFServices completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the NOFservices window starts with the last NOFServices counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOFServices.

If a transaction split by the VRFB follows a nonsplit transaction currently being executed on the SDRC side, an arbitration slot occurs on the nonsplit transaction boundary, regardless of the status of the ExtendedGrant counter. This is because the chances of a nonsplit transaction and a split transaction accessing the same SDRAM page are low. Similar behavior would be observed for a split transaction followed by a nonsplit transaction. The NOFServices counter is reloaded with its programmed value when it reaches 0.

#### 1.2.4.1.3 Internal Class Arbitration

Class 0, class 1, and class 2 internal arbitrations are performed according to the following rules:

- Within a class, a standard least-recently-used (LRU) policy is applied. The LRU thread, if not empty, is granted when an arbitration decision occurs. LRU is applied taking into account the ExtendedGrant/NOFServices counter status. Grant is given to another nonempty LRU thread only if the current thread is serviced for ExtendedGrant/NOFServices times.
- On top of the LRU policy, a high-priority group can be defined through the SMS.SMS\_CLASS\_ARBITER0[7:6] HIGHPRIOVECTOR field. The high-priority group is unique and programmable. If a high-priority thread in a class, which was previously empty, starts requesting service, the current thread that has been given grant is completely serviced as per ExtendedGrant/NOFServices strategy and then the grant is given to the high-priority thread.

##### 1.2.4.1.3.1 Interclass Arbitration

The interclass arbitration is managed using a time-varying policy driven by the following rules:

- The interclass arbitration is a PWM-like (Pulse Width Modulation) logic that defines two request-based windows:
  - Class 1 has higher priority than class 2 during M requests of class 1, where M is defined by the CLASS1PRIO parameter.
  - Class 2 has higher priority than class 1 during the next N requests of class 2, where N is defined by the CLASS2PRIO parameter. For more information on priority between classes, see [Section 1.2.6.2.2.3](#).
- The PWM counter is decremented each time the class is processing a single 64-bit request in its high-priority window.
- A class 0 request always has the highest priority. The PWM counter is frozen while class 0 requests are being serviced.
- A class 1 transaction can be serviced during the class 2 high-priority window if class 2 is not requesting service (conversely, a class 2 transaction can be serviced during the class 1 high-priority window if class 1 is not requesting service). The PWM counter is frozen when the grant is given to the thread that is not in its high-priority window.

- NOfServices/ExtendedGrant have higher priority than the PWM counter.
- The PWM counter is reloaded with M and N when it reaches 1 and an arbitration decision must be made.
- The priority order is as follows:
  - Current burst service lock (assuming subsequent burst requests available when required)
  - Class 0
  - ExtendedGrant and NOfServices atomicity (assuming subsequent burst requests available when required)
  - Class 1 if PWM priority is to class 1; class 2 if PWM priority is to class 2
  - Class 2 if PWM priority is to class 1; class 1 if PWM priority is to class 2

#### 1.2.4.1.4 Security Firewall

Access permissions can be defined in the target memory address space on a per-initiator basis. Initiators are differentiated using the interconnect ConnID extension.

Permissions are allocated to the various initiators on a per-region basis. The memory regions are programmable using a start address and an end address that are defined with 64 Kbytes granularity. Up to seven distinct regions can be defined; the software must ensure that they do not overlap.

The remaining memory space (total memory space minus the protected areas) is defined as region 0. This region has security attributes programmable in the same manner as the other regions.

Depending on whether the access is a read or a write, and depending on the in-band request qualifiers, a region may be given specific access permissions. When an access is received by the SMS, the access checked against the access attributes.

- The read permission is initiator-based and is controlled using the SMS.SMS\_RG\_RDPERMi register.
- The write permission is initiator-based and is controlled using the SMS.SMS\_RG\_WRPERMi register.
- The REQINFO bits taken into account are the incoming MReqInfo attributes: Security, debug, privilege, and attribute, along with the host parameter decoded in the SMS module (see the SMS.SMS\_RG\_ATTi[31:0] REQINFO field). For the SMS firewall, the host parameter is set for the MPU initiator and the sDMA initiator. The decoding of the host parameter, based on the MPU ConnID and sDMAConnID generic parameters (defined at design time), is done inside the SMS module.
- Whether the access is accepted (there is one valid bit for each ReqInfo pattern) can be specified for each ReqInfo pattern. ReqInfo permission is controlled using the region attributes register SMS.SMS\_RG\_ATTi[31:0] REQINFO field.

Table 1-65 lists the security ReqInfo parameters ordering.

**Table 1-65. Security ReqInfo Parameters Ordering**

Host	Privilege	Security	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	0: User 1: Supervisor	0: Public 1: Secure	0: Functional 1: Debug	0: Data Transfer 1: Opcode Fetch		
N/A <sup>(1)</sup>						0b0...000000000
0	0	0	0	0	0	0b0...000000001
0	0	0	0	0	1	0b0...000000010
0	0	0	1	0	2	0b0...000000100
					...	
0	1	1	1	0	14	0b0...000001...00
0	1	1	1	1	15	0b0...00001...000
1	0	0	0	0	16	0b0...0001...0000
1	0	0	0	1	17	0b0...001...00000
					...	
1	1	1	0	1	29	0b0010...000000
1	1	1	1	0	30	0b0100...000000

<sup>(1)</sup> Access to the region is not allowed

**Table 1-65. Security ReqInfo Parameters Ordering (continued)**

Host	Privilege	Security	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	0: User 1: Supervisor	0: Public 1: Secure	0: Functional 1: Debug	0: Data Transfer 1: Opcode Fetch		
1	1	1	1	1	31	0b1000...000000

When all SMS\_RG\_ATTi[31:0] REQINFO bits are set to 0 the access to the region is not allowed.

Set the REQINFO[0] bit to 1 when NonHost-User-Public-Functional-Data accesses are permitted in this region.

Set the REQINFO[1] bit to 1 when NonHost-User-Public-Debug-Data accesses are permitted in this region.

Set the REQINFO[31] bit to 1 when Host-Supervisor-Secure-Debug-Opcode accesses are permitted in this region.

Any bit of the SMS\_RG\_ATTi[31:0] REQINFO field corresponds to a particular combination of the five attribute bits. When all SMS\_RG\_ATTi[31:0] REQINFO bits are set to 1 the region is full-access allowed.

The security unit performs the following checks to authorize or reject an access to the external memory:

- Compute the Region ID based on the transaction address.
- Generate a violation if overlapping of security regions is detected.
- From the Region ID, get the attributes for the region that has been hit.
- Check the transaction REQINFO attributes with respect to the region attributes (security, debug, privilege, type, and host).
- Reject the transaction if the attributes are not compatible.
- From the Region ID and the transaction qualifiers (MCmd, ConnID), check the initiator permissions for performing the access (read, write).
- Reject the transaction if there is no permission.

The protection regions are organized in security priority levels (from Level 0 to Level 2) to prevent problems with overlapping region and corner cases associated with them; the lowest level has the lowest priority (see [Figure 1-48](#)).

Figure 1-48. Security Region Organization

sdrc-009

Region 0 (default region containing the whole memory space): Level 0

Region 1 (allows dynamic reprogramming of regions): Level 2

Regions 2–7 (protection regions): Level 1

Region 1 has the highest priority to perform dynamic masking of other already-programmed regions when they are reprogrammed.

Overlapping regions of the same priority level is forbidden and results in a security violation when an access to the concerned region occurs. This security violation is reported in the error-log register. Priority-level handling is done in the hardware; it does not involve any specific software development.

All transactions are checked, including those the RE has processed.

When detecting a security violation on an incoming request, the SMS respects the response ordering within the faulty thread.

A violation flag is raised internally and the MThreadID field is logged. Generation of the interconnect error response is then local to the SMS; the response buffer must be used to manage the potential response collision with regular SDRC responses.

To program a rotation context, set the security level per context through the SMS.SMS\_SECURITY\_CONTROL ROTCTXTiLOCK bits ( $i = [0:11]$ ). That is, on context  $i$ : are all transactions allowed or is access restricted to secure transactions only?

### 1.2.4.1.5 Rotation Engine

Applications must often perform image rotation between the orientation of images stored in external memory and the orientation with which they must be displayed. The device offers a hardware mechanism that allows rotation tasks to be implemented efficiently, transparent to software applications, thereby keeping the MPU and DSP CPUs free for other tasks. For a description of the RE mechanism, see [Section 1.2.6, SDRC Use Cases and Tips](#).

The SMS includes address processing support for rotated displays (90, 180, and 270 degrees). This function is realized by the VRFB submodule, also called the rotation engine (RE) in this document.

The primary goal of the VRFB is to eliminate the SDRAM page-miss penalty when reading graphics data in nonnatural raster scan order (that is, top to bottom, bottom to top, right to left).

The 2D-rotation module (the VRFB) is included as a black box that intercepts incoming requests when addressed to the virtual frame buffer. If the address of the request targets the VRFB address space, the request is sent to the RE. It processes the address and reinserts the modified request in the SMS request path. The SMS translates the virtual address into physical SDRAM addresses and reinserts a request or multiple requests in the SMS request path to the SDRC.

---

**Note:** The use of the word *virtual* does not refer to the usual CPU-related MMU concept; the word is used in a more general context of the address remapping feature, which decouples the system from the actual storage physical organization of the graphics data in the external memory.

---

The VRFB can be abstracted as a 3-port module:

- Interconnect input port
- Interconnect output port
- Configuration port; all programmable control registers are part of the SMS register file, which is described in [Section 1.2.4.1.5.3, VRFB Configuration Port](#).

#### 1.2.4.1.5.1 VRFB Input Port

The VRFB receives a 29-bit address, and two decoding signals, from the SMS module. The 29-bit address is decoded to determine the context and the rotation view of the request.

The VRFB address space is a 768 Mbytes address space split into two non-contiguous virtual address spaces:

- Address space 0: 256 MB in quarter Q1 (start address: 0x7000 0000, end address: 0x7FFF FFFF)
- Address space 1: 512 MB in quarter Q3 (start address: 0xE000 0000, end address: 0xFFFF FFFF)

It can manage up to 12 concurrent rotation contexts. [Table 1-66](#) details the address space of each context.

**Table 1-66. VRFB Contexts Virtual Address Spaces vs Rotation Angle**

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000
8	0xF000 0000	0xF100 0000	0xF200 0000	0xF300 0000
9	0xF400 0000	0xF500 0000	0xF600 0000	0xF700 0000
10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000

**Table 1-66. VRFB Contexts Virtual Address Spaces vs Rotation Angle (continued)**

Context Number	0°	90°	180°	270°
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

#### 1.2.4.1.5.2 VRFB Output Port

The VRFB output port can be a delayed copy of the input port, with the address field transformed. Depending on the rotated view that is active, an incoming transaction can also be split into several internal transactions.

The pipeline delay between the input and the output ports is three clock periods.

#### 1.2.4.1.5.3 VRFB Configuration Port

The configuration port allows 12 concurrent rotation settings.

The VRFB address space is a 768 Mbytes (256 + 512) address space split into two noncontiguous spaces. It can manage up to 12 concurrent rotation settings.

The VRFB configuration port includes all the settings required to control the 12 rotation contexts. This is an input-only port. All settings are provided from the SMS control register file.

For each of the 12 contexts, the buffer physical base address, image height and width, and pixel size can be configured through the following registers (where n is the context number, from 0 to 11):

- SMS.SMS\_ROT\_PHYSICAL\_BAn[30:0] PHYSICALBA field
- SMS.SMS\_ROT\_SIZEEn[26:16] IMAGEHEIGHT and SMS.SMS\_ROT\_SIZEEn[10:0] IMAGEWIDTH fields
- SMS.SMS\_ROT\_CONTROLn[1:0] PS field

The memory arrangement for the pixels of a frame buffer accessed through the RE is tile-based. A tile is a rectangular array of pixels. The tile size should match the page size of the SDRAM component attached to the controller for optimal performance.

The tile size is defined using the SMS.SMS\_ROT\_CONTROLn[10:8] page height (PH) and [6:4] page width (PW) fields.

The image height and image width (SMS.SMS\_ROT\_SIZEEn[26:16] IMAGEHEIGHT and [10:0] IMAGEWIDTH fields, expressed in bytes) must be multiples of the tile height and width, respectively. Some padding is required if the image size does not fit this requirement.

For a configuration example, see [Section 1.2.5.1.2, VRFB Context Configuration](#).

#### 1.2.4.1.6 Register Security

For the following register groups, use the SMS.SMS\_SECURITY\_CONTROL register to independently restrict permission to write to the SMS registers to secure accesses:

- VRFB context configuration registers (independently for each context)
- Memory-access scheduler arbitration registers
- Firewall registers, soft reset bit, error registers, and the security control register itself

Writing restrictions to the security firewall memory region registers (including SMS.SMS\_SECURITY\_CONTROL) depend on the control module configuration.

If an illegal access is attempted (for example, a nonsecure write access to a register configured as secure), a security violation is indicated to the security module. The address where the security violation occurs and the type of violation can be read from the SMS.SMS\_ERR\_ADDR and SMS.SMS\_ERR\_TYPE registers.

To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

### 1.2.4.1.7 Security Violation Reporting

The SMS firewall can detect security violations and report them to the overall system by using the following qualifiers:

- The in-band error response to a non-authorized access
  - The out-of-band error signal generation using two out-of-band error signals
- Based on the fact that there is no way to prevent the debugger from generating firewall violations during debug, and that users cannot stop checking for functional violations, two out-of-band security violation signals are set when:

- A functional violation is detected
- A debug violation is detected

These signals are asserted on each error detection from a read, write, or posted write faulty access: they are deasserted when the software clears the error bit in the SMS\_ERR\_TYPE register.

### 1.2.4.2 Module Power Saving

Power-saving is managed through the SMS.SMS\_SYSCONFIG register.

The SMS\_SYSCONFIG[4:3] SIDLEMODE field defines the power management strategy (Force Idle mode, No Idle mode, or Smart Idle mode). See [Section 1.2.4.3](#) for more details on the system power management.

By default, the internal interface clock gating strategy is enabled as the SMS\_SYSCONFIG[0] AUTOIDLE bit is set to 0x1 after reset. When all FIFO queues are empty and no ongoing transactions remain, the L3 interconnect clock is disabled inside the SMS thus reducing power consumption. The L3 interconnect clock can be disabled after a programmable delay defined in the SMS\_POW\_CTRL[7:0] IDLEDELAY bit field.

When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. It is recommended to enable this mode to reduce power consumption.

There is an internal interface clock gating strategy within the SDRC controller. This power-saving feature is always active.

### 1.2.4.3 System Power Management

The SMS can be configured through the SMS.SMS\_SYSCONFIG register to be in one of these idle modes:

- No-idle mode (the SMS.SMS\_SYSCONFIG[4:3] SIDLEMODE field is set to 0x1): The module never goes into idle state.
- Force-idle mode (the SMS.SMS\_SYSCONFIG[4:3] SIDLEMODE field is set to 0x0): The module goes into idle state immediately after receiving the request from the PRCM.
- Smart-idle mode (the SMS.SMS\_SYSCONFIG[4:3] SIDLEMODE field is set to 0x2): SidleAck is asserted once the module has confirmed there are no more outstanding transactions with the SDRC.

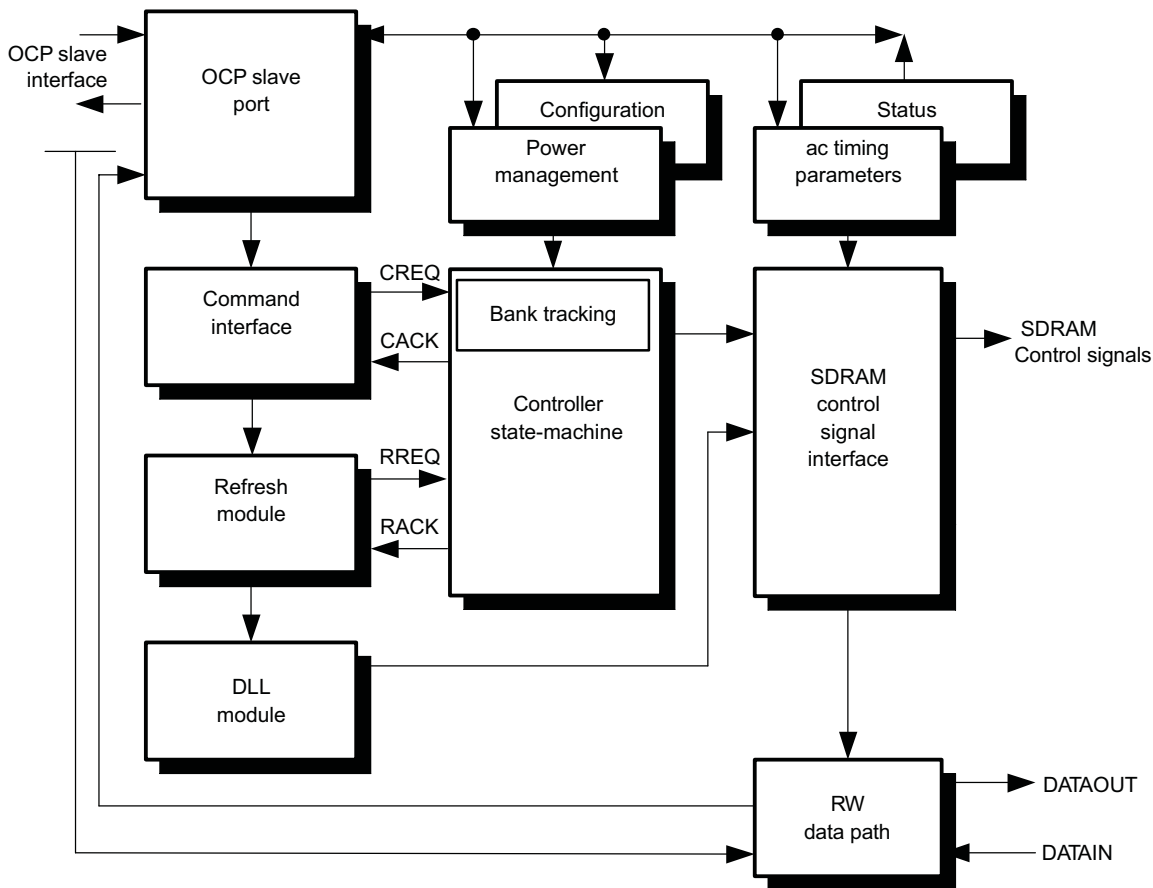

### 1.2.4.4 SDRC

The SDRC provides two configurable memory areas. Each supports low-power DDR SDRAM from 16 Mbits to 2 Gbits, depending on the memory organization.

Flexible row/column addressing schemes are possible with 2-bank support for 16 Mbits and 32 Mbits memories, and 4-bank support for 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, and 2 Gbits memories.

[Figure 1-49](#) shows the architecture of the SDRC.

Figure 1-49. SDRC Architecture

sdrc-010

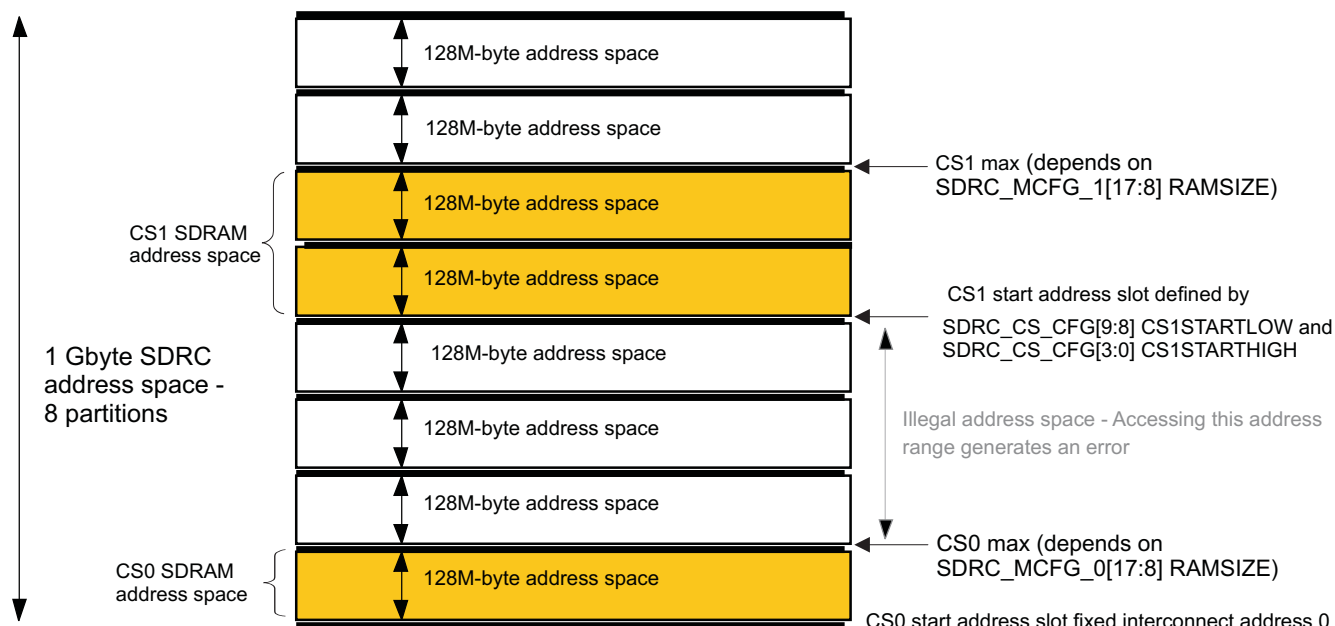

#### 1.2.4.4.1 CS0-CS1 Memory Spaces

##### 1.2.4.4.1.1 Chip-Select 0 Start Address

- CS0 always starts at address 0 with respect to the local interconnect address.
- The valid CS0 range is 0 - CS0max, where CS0max is defined in the SDRC.SDRC\_MCFG\_p[17:8] RAMSIZE field where p=0 (for CS0), and by the number of banks.

##### 1.2.4.4.1.2 Chip-Select 1 Start Address

- CS1 start address is programmable.
- The default base address for CS1 after reset is defined in the register description.
- The SDRC 1 Gbyte / 8 Gbits address space is segmented so that 7 possible CS1 start address locations (8 in total minus 1 reserved for CS0) are defined by the SDRC.SDRC\_CS\_CFG[3:0] CS1STARTHIGH field as shown in Figure 1-50.
- Each 128M-byte address space is also segmented into 32M-byte address spaces defined by the SDRC.SDRC\_CS\_CFG[9:8] CS1STARTLOW field so that 64 possible CS1 start address locations are defined by the SDRC.SDRC\_CS\_CFG[3:0] CS1STARTHIGH and SDRC.SDRC\_CS\_CFG[9:8] CS1STARTLOW fields.
- The valid CS1 range is:  
CS1 start address slot - CS1max, where CS1max is defined by SDRC.SDRC\_MCFG\_p[17:8] RAMSIZE where p=1 (for CS1) and SDRC.SDRC\_CS\_CFG registers.

**Figure 1-50. CS0/CS1 Chip-Select Start Address Slots**

sdrc-011

### 1.2.4.4.1.3 SDRAM Memory Combinations on CS1 and CS0

The SDRAM data bus width on each CS is determined by the SDRS.SDRS\_SHARING[11:9] CS0MUXCFG and SDRS.SDRS\_SHARING[14:12] CS1MUXCFG fields of the memory-sharing registers.

**Note:** For DDR connectivity, refer to the device specific data manual.

### 1.2.4.4.2 Bank Tracking

The main state-machine controls all the accesses to external memories.

The SDRS contains hardware for tracking open pages. Up to four open pages are tracked per CS, for a maximum of eight open pages tracked.

To efficiently pipeline accesses, the SDRS includes a request look-ahead FIFO that analyzes interconnect requests with respect to the status of the target banks. A bank status can be any of the following:

- Bank open on another row
- Bank closed
- Bank open on the same row

The SDRS state-machine generates the appropriate sequence of memory commands. All precharge and active commands are hidden as much as possible, to optimize the memory bandwidth usage.

The look-ahead FIFO depth is  $9 \times 64$ -bit requests, with a limit of four different transactions. As soon as the look-ahead FIFO stores four complete transactions or when it is full, the SCmdAccept is deasserted and any incoming request is blocked.

Requests sent to the SDRS are treated in order. The four transactions limit in the SDRS look-ahead FIFO ensures that high-priority requests performance is not hampered by a succession of SDRAM page close/page open cycles due to previous lower priority requests already accepted by the SDRS. With this limit, requests not accepted by the SDRS will have to go through the SMS arbitration at a later time. If a high-priority request has arrived in the SMS in the mean time, it will be passed to the SDRS before any lower-priority request, as defined in the regular SMS arbitration scheme.

### 1.2.4.4.3 Address Multiplexing

A flexible address scheme allows for the support of any new type of SDRAM address multiplexing and density.

The programming model has changed but is still compatible with the legacy fixed address scheme. Both chips, hence both CS must use the same address scheme (fixed or flexible), but can use different address multiplexing configurations.

A dedicated bit controls the address scheme used: the legacy fixed address scheme or the new flexible address scheme:

- The legacy fixed address scheme is selected when the SDRC.SDRC\_MCFG\_p[19] ADDRMUXLEGACY bit is set to 0 (where p = 0 or 1 for SDRC CS0 or CS1).
- A new flexible address-muxing scheme configuration is selected with the SDRC.SDRC\_MCFG\_p[19] ADDRMUXLEGACY bit set to 1 (where p = 0 or 1 for SDRC CS0 or CS1).

To use this new flexible address scheme, configure the row address width and the column address with the SDRC.SDRC\_MCFG\_p[26:24] RASWIDTH and SDRC.SDRC\_MCFG\_p[22:20] CASWIDTH fields.

For more information about fixed address multiplexing configurations for SDRAM components, see [Section 1.2.2.2.3, Address Multiplexing](#).

### 1.2.4.4.4 Bank Allocation Setting

#### 1.2.4.4.4.1 System Address Decoding

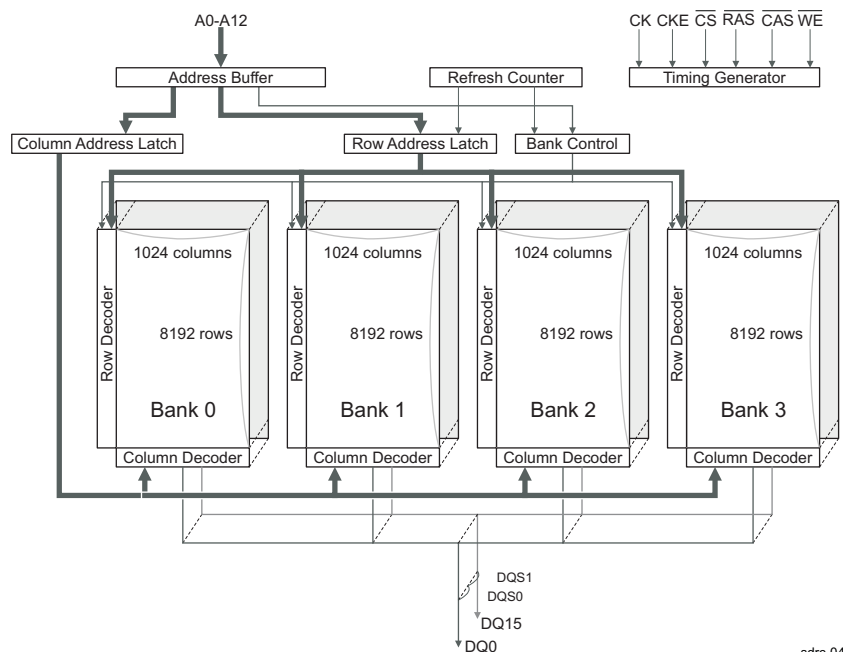

The SDRC has a 64-bit slave interface connected to the L3 main system interconnect. The regular allocation is to see the system address bus as the concatenation bank-row-column. The SDRC controller translates the interconnect request (read or write to memory for instance) into a series of commands and bank, row, column signals. The commands are sent to the external SDRAM through the sdrc\_ncs, sdrc\_nras, sdrc\_ncas and sdrc\_nwe signals. The bank, row and column addresses are sent through sdrc\_a and sdrc\_ba with the associated command. Those words can be defined as follow:

- Bank: the address of one of the four (or two) banks
- Row: the address of a page
- Column: the address of a word in a page

The bank signals are used to select which of the bank is accessed when transferring data from or to the SDRAM. In the first cycle, the SDRAM memory latches the row address (nRAS low): the adequate bank and row are activated. Next cycle, the SDRAM memory latches the column address (nCAs low): the adequate column is activated. The address is hence decoded: memory cells are sensed by sense amplifier and data is read from or written to output buffers.

[Figure 1-51](#) shows a block diagram of a 512 Mbits SDRAM memory (8M x 16 x 4 banks). The data bus DQ[15:0] has a 16-bit width. Rows are addressed through A0-A12 (8192 rows) and columns through A0-A9 (1024 columns).

**Figure 1-51. SDRAM Controller Block Diagram**

sdrc-042

#### 1.2.4.4.2 SDRC Controller Commands

Before any read or write command can be issued to a bank in the external memory, a row in that bank must be opened. This is accomplished by the active command, by which both the bank and the row are selected. More than one bank (up to 4 according to the memory used) can be active at any time. Once a row is opened, a read or write command can be issued to that row. The row remains active until a precharge or read/write to another row in the same bank or refresh to the bank.

Autorefresh command is used during normal operation mode. This command is non-persistent, i.e. it must be issued each time a refresh is required. The device requires a refresh of all rows in a periodic interval. This command takes some time (according to the memory used) and during this phase no read or write command can be processed. A precharge-all (i.e. precharge command impacting all banks) is issued before any autorefresh sequence.

An active command to a row of a bank for which another row is already active can only be issued after the previous row has been closed. The precharge command is used to deactivate the open row in a particular bank. The bank is available for a subsequent row access some time after the row precharge command is issued. A minimum time is needed to close and to open a new row.

A subsequent active command to another bank can be issued while the first bank is being accessed without closing the row in the first bank. This results in a reduction of row access time in the same bank. In this case, it is not necessary to deactivate (with a precharge command) the row in the other banks. Up to 4 banks, depending on the memory used, can be activated at the same time. In each bank, one row can be selected at a time.

#### 1.2.4.4.4.3 The BANKALLOCATION Parameter

In order to optimized SDRAM memory accesses in a throughput point of view, the SDRC controller supports various bank-row-column allocation. The bank-row-column allocation choice depends on many parameters such as the number of initiators in the use case, the memory usage (accesses bandwidth, frequency) and so on.

The SDRC controller support the regular allocation where the system address bus is seen as the concatenation bank-row-column but it also supports two other types of allocation. The SDRC\_MCFCG\_p[7:6] BANKALLOCATION field (where p = 0 or 1 for CS0 or CS1) selects the type of allocation. This feature modifies the bank, row, and column address decoding order:

- BANKALLOCATION = 0x0: Bank-row-column
- BANKALLOCATION = 0x1: Bank1-row-bank0-column
- BANKALLOCATION = 0x2: Row-bank-column

Only the flexible address-muxing scheme allow choosing different bank mapping allocations throughout the BANKALLOCATION parameter, i.e. the legacy address-muxing scheme does not.

The flexible address-muxing scheme (SDRC\_MCFCG\_p[19] ADDRMUXLEGACY = 0x1) allows choosing different bank mapping allocations. The SDRC.SDRC\_MCFCG\_p[7:6] BANKALLOCATION field (p = 0 or 1 for CS0 or CS1) defines the ordering of the bank, column and row decoding of the incoming system address. The BANKALLOCATION field can be set on a CS basis.

In usual allocation the system address bus is seen as a concatenation of bank-row-column. For instance, let's consider the SDRAM used in [Section 1.2.6.3, Typical SDRC connection to an External SDRAM Device](#) section: a 512 Mbits SDRAM (8M x 16 x 4 banks). The system address received from the interconnect into the SDRC is composed of:

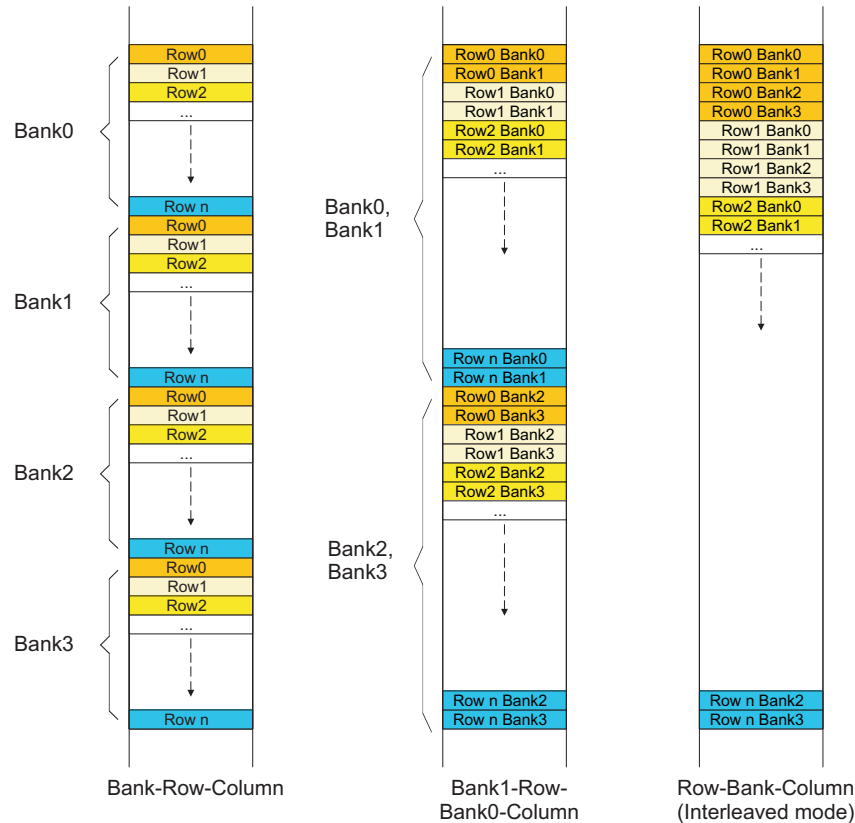

- 2 system address bits used as the bank address (going to SDRC controller sdrc\_ba[1:0] pins)
- 13 system address bits used as the row address (going to SDRC controller sdrc\_a[12:0] pins)
- 10 system address bits used as the column address (going to SDRC controller sdrc\_a[12:0] pins)

Setting the BANKALLOCATION field to 0x1 or 0x2 changes the order of the system address decoding, as shown in [Figure 1-52](#).

**Figure 1-52. Address Multiplexing Scheme According to BANKALLOCATION**

[Figure 1-53](#) compares Bank-row-column and Row-bank-column memory accesses.

**Figure 1-53. Simplified View of Bank-Row-Column vs Row-Bank-Column Bank Allocation**

sdr\_044

The latency to charge another row in the same bank (i.e. to close the opened page and to open another one) is bigger than the latency involved with an access to a given row in another bank. By moving bank select signals ahead of column and after row addresses, bank interleaving is guaranteed to happen more often. More frequent use of the interleaved mode means less overall SDRAM access time and, thus, yields to better overall performance.

In some use case, several initiators access to the same bank (bank0 for instance) in external SDRAM memory at a time. With this kind of scenario, a lot of penalties are added because of rows opening and closing. The BANKALLOCATION setting improves the latency for reading and writing operations, by optimizing memory accesses through the reduction of deactivate sequence usage, hence by reducing time penalties.

The bank1-row-bank0-column allocation is a good compromise between the legacy bank allocation (bank-row-column) and the full interleaving bank allocation (row-bank-column). In some use case, it might be necessary to keep only half of the memory refreshed (on bank0 and bank1 for instance) while the two other banks are unused. In full interleaving bank allocation the memory must be refreshed through the self-refresh mode, while with bank1-row-bank0-column the memory can be refreshed either through self-refresh mode or through partial array self-refresh mode.

### CAUTION

Do not use the bank interleaving feature in the SDRC with OneDRAM memory because this feature swaps bank bits and address bits; it does not match them with fixed address registers of the OneDRAM. The SDRC.SDRC\_MCFG\_p[7:6] BANKALLOCATION bit field must be equal to 0x0 for a OneDRAM memory.

In the next paragraph, an example of latency is given based on the Mobile DDR SDRAM 512-Mbit SDRAM memory data sheet. [Table 1-67](#) gives the duration for some AC timing parameters. The frequency used in the example is 133 MHz, that is  $tCK = 7.5$  ns. The CAS latency = 3.

**Table 1-67. Mobile DDR SDRAM AC Timings Parameters**

AC Timing Parameter	Description	Duration (ns)
tRFC	Autorefresh cycle time	80 (min)
tRP	Row precharge time	22.5 (or 3 tCK)
tRC	Row cycle time	67.5 (or 9 tCK)
tRAS	Row active time	45 (or 6 tCK)
tRCD	nRAS to nCAS delay time	22.5 (or 3 tCK)
tRRD	Row active to row active delay time	15 (or 2 tCK)

The latency to access another row in the same bank depends on tRP and tRAS timings because a precharge command followed by an active command must be issued. Hence, 6 tCK are needed to close the current row and to open another one.

When accessing another bank, the latency to access another row depends on tRAS timing only because the closing of the current row is not mandatory. In other words only an active command must be issued. Hence, 3 tCK are needed to open another row in a different bank.

Single initiator use case:

When the initiator wants to access a page in a bank for the first time, it only opens this page. It takes 3 tCK. When the initiator is done with this page, it closes this page and opens another one. It takes 6 tCK.

Two initiators use case:

When one initiator wants to access a page in the same bank, it must necessarily close the current page and open the page he wants to access. It takes 6 tCK.

When one initiator wants to access a page this time in another bank, there could be less page opening and closing. For instance if the initiator wants to open a page in another bank where no page is opened it takes only 3 tCK rather than 6 tCK if it was another page in the same bank.

#### 1.2.4.4.5 Data Multiplexing During Write Operations

##### 1.2.4.4.5.1 External Bus Combinations

The SDRC pin allocation scenarios are provided in [Table 1-68](#). These scenarios are defined on a per-CS basis for maximum flexibility. The pin allocation configurations allow implementation of combinations of the 16-/32-bit external interfaces listed in this table. The data multiplexer receives a 64-bit word from the SDRAM command queue and partitions the data into a series of 16-bit or 32-bit accesses. The data multiplexer also steers the data to the appropriate data lane. The data partitioning and data steering are determined by the SDRC.SDRC\_SHARING[11:9] CS0MUXCFG and SDRC.SDRC\_SHARING[14:12] CS1MUXCFG fields.

**Table 1-68. SDRC Data Lane Configurations**

Device pins	sdrc_d[31:24]	sdrc_d[23:16]	sdrc_d[15:8]	sdrc_d[7:0]	
	DataLane[31:16]		DataLane[15:0]		
	DQS3	DQS2	DQS1	DQS0	
	DQM3	DQM2	DQM1	DQM0	SDRC.SDRC_SHARING[14:9] CSnMUXCFG field
	D[31:0]				0x0, 0x1
	D[15:0]				0x2, 0x7
			D[15:0]		0x3
					0x4, 0x5, 0x6: Reserved

### 1.2.4.4.5.2 Endianness-Aware Unpacking

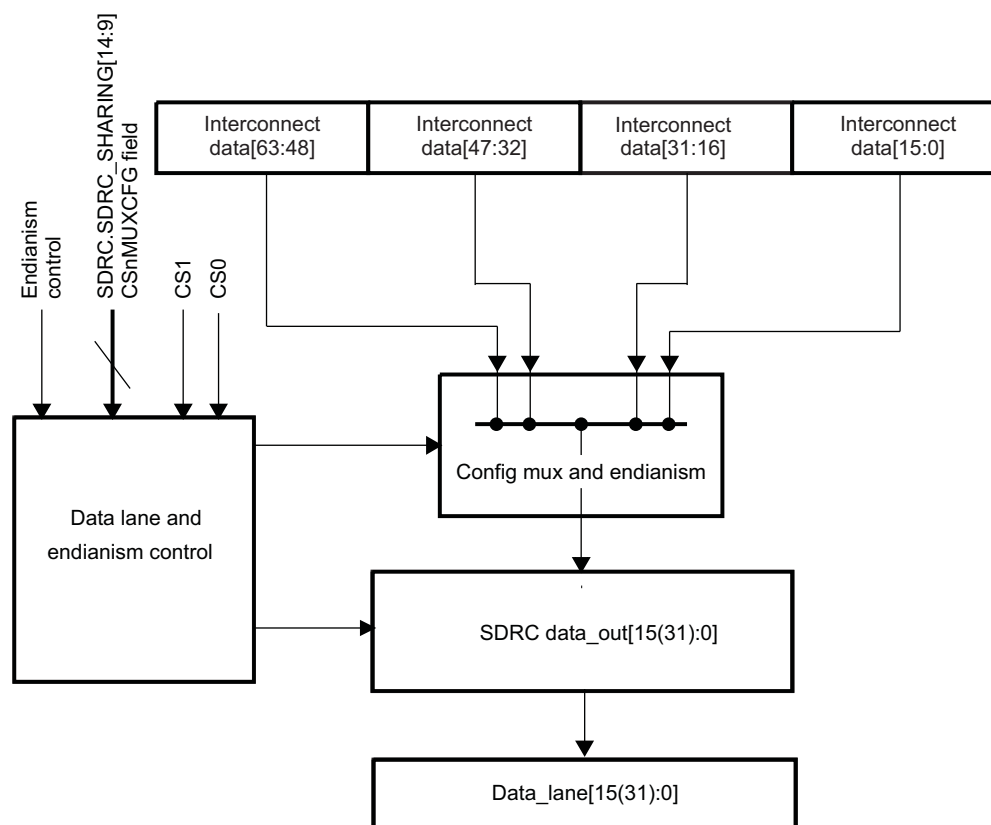

Data transactions can be either big or little endian; the transaction endianness is determined by an in-band interconnect qualifier. Muxing 64-bit data to 16-/32-bit data is performed according to this qualifier.

For a 64-bit interconnect little-endian write transaction on a 16-/32-bit memory, Data[15(31):0] is written at the lowest memory address, and Data[63:48(32)] is written at the highest memory address.

For a 64-bit interconnect big-endian write transaction on a 16-/32-bit memory, Data[15(31):0] is written at the highest memory address, and Data[63:48(32)] is written at the lowest memory address.

Figure 1-54 shows the data multiplexing scheme.

**Figure 1-54. Data Multiplexing Scheme**

sdrc-012

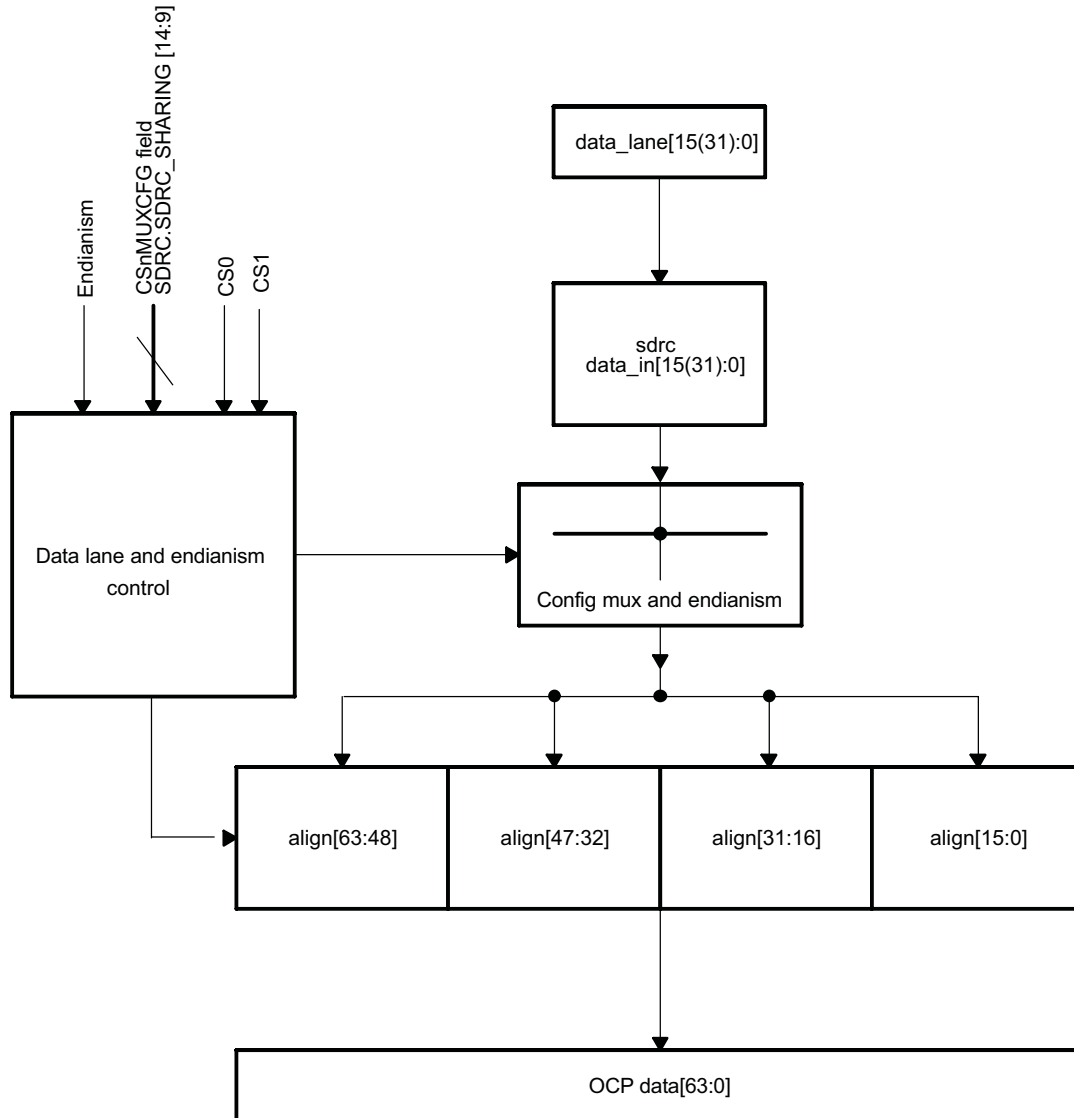

### 1.2.4.4.6 Data Demultiplexing During Read Operations

#### 1.2.4.4.6.1 External Bus Combinations

The SDRC pin allocation scenarios are shown in Table 1-68. These scenarios are defined on a per-CS basis for maximum flexibility. The pin allocation configurations allow implementation of combinations of 16-/32-bit external interfaces. The data demultiplexer receives 16-/32-bit data from the relevant SDRC data lane, and then performs a data packing function. The packing function formats the data into 64-, 32-, 16-, or 8-bit format. The data demultiplexer also steers the data from the appropriate data lane. The data partitioning and data steering are determined by the SDRC.SDRG\_SHARING[11:9] CSOMUXCFG and SDRC.SDRG\_SHARING[14:12] CS1MUXCFG fields.

Figure 1-55 shows the data demultiplexing scheme.

Figure 1-55. Data Demultiplexing Scheme

#### 1.2.4.4.6.2 Endianness-Aware Packing

Data transactions can be either big or little endian; their endianness is determined by an in-band interconnect qualifier. Demuxing 16-/32-bit memory data to 64-bit interconnect data is performed according to this qualifier.

For a 64-bit interconnect little-endian read transaction on a 16-/32-bit memory, Data[15(31):0] is read from the lowest memory address, and Data[63:48(32)] is read from the highest memory address.

For a 64-bit interconnect big-endian read transaction on a 16-/32-bit memory, Data[15(31):0] is read from the highest memory address, and Data[63:48(32)] is read from the lowest memory address.

To preserve data integrity in all situations, that is, regardless of the effective scalar size of the transferred data (byte, Word16, Word32, or DWord64), the endianness specified during the read operation must match that specified during the write operation. If there is no match, the packing and unpacking operations are not consistent. There is no attempt to perform endianness conversion in the SDRC; only endian-aware width conversion is performed.

#### 1.2.4.4.7 Refresh Management

Refresh management can be divided as follows:

- Self-refresh management
- Autorefresh management (programmable refresh period)

##### 1.2.4.4.7.1 Self-Refresh Management

Self-refresh is entered to place an attached SDRAM into an autonomous refresh mode, typically when the OMAP Applications Processor enters an idle mode and switches the SDRAM clock off.

In self-refresh, the SDRAM supplies the row address generation required to refresh and retain data in the absence of external clocking.

Self-refresh can be entered using any of the following methods:

- Manually, under software control per CS
- Upon a reset event: automatically on a warm reset event (if the SDRC is programmed to enter self-refresh on warm reset)
- Upon a hardware request: automatically on an idle request sent by the system power manager (if the SDRC is programmed to enter self-refresh on idle request)
- Automatically after a (programmable) period of inactivity on the interconnect interface (if enabled by setting the SDRC.SDRC\_POWER\_REG[5:4] CLKCTRL field to 0x2)

Self-refresh can be exited as follows:

- Manual software command (exit from self-refresh mode; see [Section 1.2.5.3.4, DLL/CDL Configuration](#))
- Automatically after receiving a read or write transaction to access memory

##### 1.2.4.4.7.2 Autorefresh Management

When autorefresh is enabled, a programmable hardware counter within the SDRC generates a periodic event that triggers either a single refresh or a burst of consecutive refresh commands. This is the standard refresh mode used when the system is active, while the running applications regularly access the SDRAM.

An autorefresh command can also be applied using the SDRC.SDRC\_MANUAL\_p register (see [Section 1.2.5.3.4, DLL/CDL Configuration](#)). This method can be used to generate a device-specific initialization sequence after power up or after the memory device exits from a low-power mode (self-refresh or deep-power-down).

The autorefresh request period is a user-controlled parameter programmed to meet the specification of the memory devices. Each time an autorefresh request is issued, the SDRC can service the autorefresh using any of the following commands:

- Single autorefresh command
- Burst of four autorefresh commands
- Burst of eight autorefresh commands

When a burst of four or eight is selected, the programmed period value is automatically scaled in hardware by 4 or 8. Consequently, the value to be programmed does not depend on the selected burst length.

##### 1.2.4.4.8 System Power Management

Unlike the SMS, the SDRC can be configured only in smart-idle mode by setting the SDRC.SDRC\_SYSCONFIG[4:3] IDLEMODE field to 0x2. Once all asserted output interrupts are acknowledged, the SDRC goes into idle state after it receives the request from the PRCM module.

The SDRC acknowledge is conditioned by the internal activity of the SDRC.

- Note:** As soon as the SDRC goes out of idle state, stalled accesses can be accepted and processed:
- In DDR fixed delay mode, the accesses will be processed (unstalled) after expiration of `MODEFIXEDEDELAYINITLAT`.

#### 1.2.4.4.9 Power-Saving Features

In the SDRC there are three ways to save power and they can be applied simultaneously:

- Page opening/closure policy
- Dynamic low-power mode
- Static low-power mode

##### 1.2.4.4.9.1 Page Opening/Closure Policy

The OMAP Applications Processor supports only one page policy. The `SDRC.SDRC_POWER_REG[0]` `PAGEPOLICY` bit must be set to 1.

The SDRC tracks open pages, if any, and determines whether the current access is to an open or a closed page. If the accessed page is open, the SDRC executes the access immediately. The SDRC performs the following procedure:

1. If the current page is already open on this bank the SDRC automatically issues a *precharge* command to close that bank.
2. Opens the accessed page by issuing an *active* command to that bank
3. Executes the access by issuing a *read* or *write* command

Up to four pages can be open simultaneously with a limit of one page per bank. The pages remain open until one of the following occurs:

- New read or write request to another page in the same bank
- Autorefresh request (a *precharge all* command is issued first)
- Self-refresh entry request (a *precharge all* command is issued first)
- Manual *precharge all* command

##### 1.2.4.4.9.2 Dynamic Low-Power Operating Modes

The dynamic low-power operating modes of the SDRC are designed to:

- Control the external SDRAM clock(s)
- Control the internal clock gating of the SDRC when the interconnect interface is idle
- Control the self-refresh functionality

The external SDRAM is controlled through the `SDRC.SDRC_POWER_REG[3]` `EXTCLKDIS` and `SDRC.SDRC_POWER_REG[2]` `PWDENA` bits. The `EXTCLKDIS` bit is used to disable the external clock when no access is ongoing on the memory interface, whereas the `PWDENA` bit is used to activate the power-down mode of the target memory by pulling the relevant `CKE` low each time the memory interface is idle.

When the `PWDENA` bit is enabled but the `EXTCLKDIS` bit is not enabled, the SDRC still provides a free-running clock to the external memories: clock gating is done internal to the memory component for power savings.

`EXTCLKDIS` should only be modified when no access is in progress on the SDRAM interface. Software control is required to make sure the interface is idle.

`CKE` is dynamically controlled based on the current memory command. There is a zero-latency penalty when this mode is enabled.

The SDRC has three modes of automatic internal clock-gating behavior when the interconnect interface is idle, that is. there are no outstanding active transactions in progress. These modes are controlled through the `SDRC.SDRC_POWER_REG[5:4]` `CLKCTRL` and `SDRC.SDRC_POWER_REG[23:8]` `AUTOCOUNT` fields.

- Mode 0: The autoclock gating feature is disabled. No internal clock gating is performed in the SDRC in response to the detection of an idle state on the interconnect interface.
- Mode 1: A 16-bit counter starts decrementing when an interconnect idle condition is detected. The counter start value is loaded from the AUTOCOUNT 16-bit field. When this counter times out, internal clock gating within the SDRC is enabled.
- If an interconnect active command is received before the counter times out, or if an internal autorefresh request is issued, the procedure is aborted, the counter stops decrementing, and the request is serviced immediately.
- Mode 2: This mode is similar to mode 1, but before the internal clock gating, the SDRC places the SDRAM into self-refresh mode and turns off the external SDRAM clock. This is the lowest power mode.

To achieve maximum power savings, TI recommends the use of the PWDENA-, EXTCLKDIS-, and CLKCTRL-related features.

Table 1-69 explains the different power-saving configurations that can be programmed with the SDRC.SDRC\_POWER\_REG[3] EXTCLKDIS, SDRC.SDRC\_POWER\_REG[2] PWDENA, and SDRC.SDRC\_POWER\_REG[5:4] CLKCTRL bits.

**Table 1-69. Dynamic Power Saving Configurations**

CLKCTRL	EXTCLKDIS	PWDENA	CKE	External SDRC CLK <sup>(1)</sup>	SDRAM State	Latency When Exiting Power Mode
0	0	0	Always high	Always on	Keep previous state	
0	0	1	Low when no access	Always on	Power-down	Zero-latency penalty
0	1	0	Always high	Off when no access	Keep previous state	
0	1	1	Low when no access	Off when no access	Power-down	One cycle penalty
1	0	0	Always high	Always on	Keep previous state	
1	0	1	Low when no access	Always on	Power-down	Zero-latency penalty
1	1	0	Always high	Off when no access	Keep previous state	
1	1	1	Low when no access	Off when no access	Power-down	One cycle penalty
2	0	0	Low when no access	Off when no access after AUTOCOUNT expiration	Enter self-refresh after AUTOCOUNT expiration	
2	0	1	Low when no access	Off when no access after AUTOCOUNT expiration	Enter self-refresh after AUTOCOUNT expiration	
2	1	0	Low when no access	Off when no access	Enter self-refresh after AUTOCOUNT expiration	
2	1	1	Low when no access	Off when no access	Enter self-refresh after AUTOCOUNT expiration	

<sup>(1)</sup> EXTCLK can be set to 1 all the time for power optimization purposes, except when manual commands are sent. In this case, users must set EXTCLKDIS to 0 to ensure that a clock signal is provided to the memory device.

**Note:** When connected to a DDR memory, the SDRC never gates the clock provided to the DLL components, so that the DLL remains locked during these idle modes. This avoids the maximum of 500 clock cycles latency required for relocking the DLL when the DLL clock is switched off.

All settings for the power-saving features are common to the two CSs. When two CSs are used, however, only the accessed CS exits self-refresh or deep-power-down mode.

If the SDRC.SDRC\_POWER\_REG[6] SRFONIDLEREQ bit is enabled, the SDRC enters self-refresh

mode on a hardware idle request from the PRCM. The memory clock is automatically switched off, after which the SDRC sends an acknowledge back to the PRCM. In this situation, the power manager can switch the SDRC clock off. Therefore, if the SDRC is connected to a DDR memory, and if the DLL is enabled and in TrackingDelay mode, the SDRC waits for the lock status bit of the DLL to be asserted before accessing the memory when the system exits the idle state. The WAKEUPPROC bit of the SDRC\_POWER\_REG register enables the SDRC to automatically wait for 500 cycles (DLL relocking maximum time) before accessing the memory instead of using the LOCK signal. These 500 wait cycles are obeyed only when the DLL is set in TrackingDelay mode. For DLL ModeFixedDelay mode, the access is processed immediately. This mechanism is independent of the CLKCTRL field.

---

**Note: DLL Behavior Upon a Warm Reset Assertion:**

Upon a warm reset event, the DLL is disabled and is no longer locked (SDRC\_DLLA\_CTRL[3] ENADLL and SDRC\_DLLA\_STATUS[2] LOCKSTATUS bits are reset). The input clock runs at low frequency. To prevent the DLL from remaining unlocked, the software must re-enable the DLL by setting the ENADLL bit to 1. Then, after a maximum of 500 cycles latency required to relock it, the DLL is locked (LOCKSTATUS bit = 1). Thus, the DLL is locked on the stable input clock and, therefore, ready to process incoming requests so that the SDRC can again access the memory.

---

#### 1.2.4.4.9.3 Static Low-Power Operating Modes

The software-driven controls for low-power operation modes include:

- Possibility to put the memory in self-refresh using the manual command register (SDRC.SDRC\_MANUAL\_p (where p = 0 or 1 for SDRC CS0 or CS1). Each CS can be controlled independently. If both CSs are in self-refresh, the external SDRAM clock can be switched off by setting the SDRC.SDRC\_POWER\_REG[3] EXTCLKDIS control bit to 1. Self-refresh can be exited automatically if an access is initiated onto the CS. Only DPD must be exited manually.
- Possibility to put the memory in deep-power-down mode, if supported by the SDRAM, using the manual command register. Each CS can be controlled independently. The external SDRAM clock can be switched off if both CSs are either in self-refresh or deep-power-down mode by setting the SDRC.SDRC\_POWER\_REG[3] EXTCLKDIS control bit to 1. Another manual command must be used for the memory to exit deep-power-down mode. After a memory exits from that mode all data are lost, and a full initialization sequence must be sent to the device, before it can be used.

#### 1.2.4.4.10 SDRC Power-Down Mode

In some applications, the SDRC power domain can be powered down while the external memory is in self-refresh mode.

When the SDRC is powered off, an isolation stage prevents an unwanted exit from self-refresh when the context is restored. SDRC outputs that control the SDRAM are set to maintain self-refresh or deep-power-down (CKE low).

When a reset occurs, the default reset state of the SDRC is power-down enable (PDE).

When exiting the off mode:

- Power is restored to the SDRC.
- The software reconfigures all registers. If the NOMEMORYMRS bit is set, the MR and EMR registers can be set through the SDRC.SDRC\_MR\_p and SDRC.SDRC\_EMR2\_p registers (see [Section 1.2.4.5, Mode Registers](#)).
- Exit from self-refresh mode is achieved through the SDRC.SDRC\_MANUAL\_p CMDCODE field. Because exit from the self-refresh field is unconditional (that is, the current state of the SDRC state-machine is not considered), ensure that autorefresh is disabled.

Once the context is successfully restored, the software can reinitialize the SDRAM or return the SDRAM to self-refresh. When the device successfully exits self-refresh, autorefresh must be re-enabled.

#### 1.2.4.4.11 Controlled Delay Line

The DLL/CDL module (Smartreflex-compatible) is a hard macro composed by one master delay-locked loop (DLL) and five slave controlled delay lines (CDL). It is used to generate precise delays suitable for DDR read and write operations. DLL delays are tracked at high frequency on process dispersion, and voltage and temperature variations (PVT) .

A CDL is a component with a clock input signal, a clock output signal, and a delay value input. The output signal is the input signal delayed according to the delay value.

The DLL output is a command that controls the CDLs (plus the controlled voltage) and assures an output signal with 90-degree delay with respect to its input signal. The DLL contains five CDL blocks.

##### 1.2.4.4.11.1 Purpose of the DLL/CDL Module

In DDR applications, the DLL and CDL combination helps provide a data strobe (DQS) with a delay suitable to the main read and write RAM operations that exceed 83 MHz. The DLL functions within a locking range of 83 to 166 Mhz. Below 83 MHz, the DLL must be used in unlocked mode. For lower clock frequencies, set the DLL to bypass mode.

DLL/CDL is used to delay the incoming DQS in case of DDR read, or delay the output DQ (data lines) in case of DDR write (and, hence, to increase the ac timing margin).

DQS is propagated with the data (thus reducing the impact of the propagation delay) and is used by the receiver to sample the data.

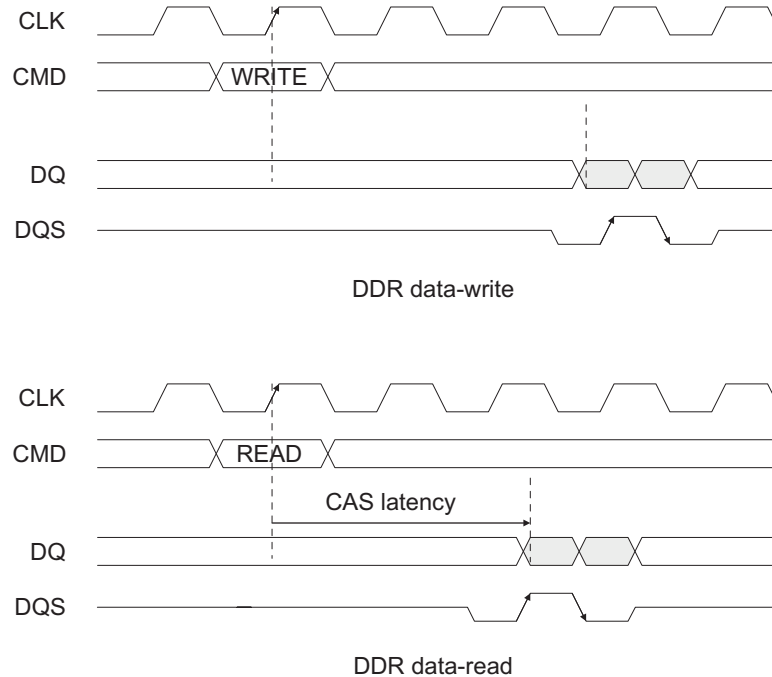

The DLL/CDL combination minimizes the negative effects caused by skews and jitters of clock signals. The delay introduced by the CDL base unit depends on PVT conditions. Moreover, the CDL timing delay is not a linear function of the DLL counter offset. By means of the DLL feedback loop, the delay value is updated in real time and is adjusted according to voltage and temperature variations.

DDR interfaces transmit data on both edges of the DQS bidirectional data strobe. Address and control signals transmit at half the data frequency (that is, at the DDR clock frequency) and latch only on the rising edge of the transmit clock.

The bidirectional data strobe (DQS) is transmitted externally, along with data, for use in data capture at the receiver. `sdrc_dqs[3:0]` is an SDRC I/O that connects the SDRC with DDR SDRAM DQS pins. See [Figure 1-42](#) for an overview of DDR SDRAM connection with the SDRC controller. DQS is transmitted by the DDR SDRAM during reads and by the SDRC during writes. DQS is edge-aligned with data for reads and center-aligned with data for writes, as shown in [Figure 1-56](#). Another DDR write path can be selected with the `WRITEDDRCLKX2DIS` bit of the `SDRC_DLLA_CTRL` register. This path uses a double frequency input clock coming from the PRCM to achieve proper generation of MDDR write data bytes, center-aligned with the corresponding DQS lines. It is recommended to set the `WRITEDDRCLKX2DIS` bit to 0 to use this path.

[Figure 1-56](#) shows the generic DDR data-write and data-read waveforms.

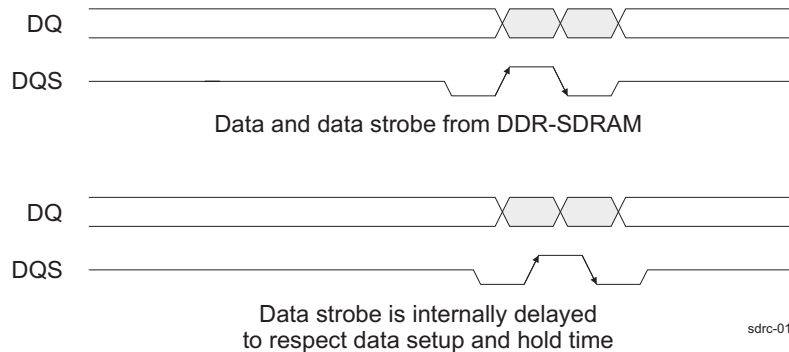

**Figure 1-56. Generic DDR Data-Write and Data-Read Waveforms**

sdrc-014

Figure 1-57 shows the DDR SDRAM data and data strobe DQS signals exiting synchronously and in phase during a data read. DQS signals are used to sample incoming data internally and, hence, must be delayed to create data-setup and data-hold time at the synchronization flip-flop inputs, as shown in the bottom waveforms of Figure 1-57. This is the goal of the DLL/CDL module.

**Figure 1-57. Required Synchronization DFF Input Signals**

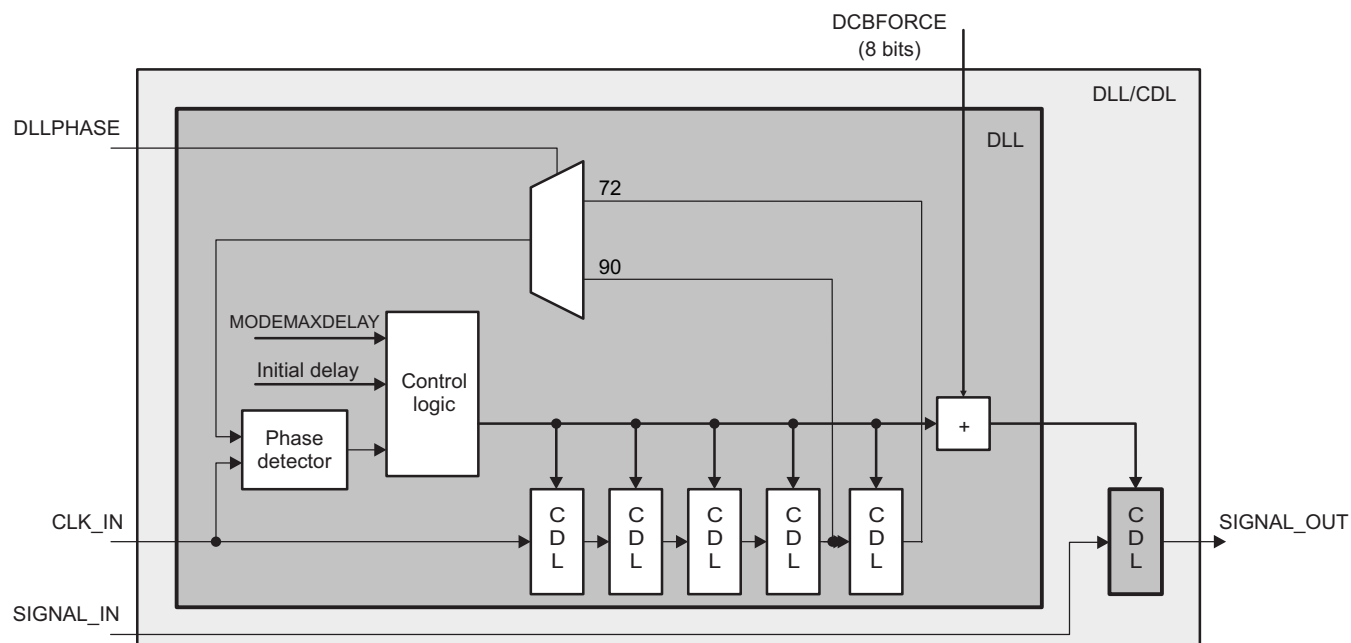

sdrc-015

**Figure 1-58** shows how the DLL/CDL interacts with the synchronization flip-flops. See [Table 1-68](#) for more information on device pins and SDRC data-lane configurations regarding DQS.

sdrc-016

Figure 1-59 shows a simplified block diagram of the DLL/CDL module.

**Figure 1-59. Simplified DLL/CDL Block Diagram**

sdrc-017

The DLL circuit contains five delay elements in series. Hence, the DLL output code and regulator output voltage determine a delay equivalent to one fifth of the reference input period in a stand-alone DLL/CDL (those CDLs are delay elements integrated into the DLL and are not shown in [Figure 1-58](#)). In other words, DLL/CDL delay is equivalent to either 72 or 90 degrees, i.e. respectively to a quarter or a fifth of a DDR clock period. It is recommended for read accesses to use 72 degrees (SDRC\_DLLA\_CTRL[1] DLLPHASE = 0x0) and for write accesses 90 degrees without DLL/DCDL (SDRC\_DLLA\_CTRL[1] DLLPHASE = 0x1 and SDRC\_DLLA\_CTRL[3] ENADLL = 0x0).

## 1.2.4.5 Mode Registers

### 1.2.4.5.1 Mode Register (MR)

It is a 12-bit register and controls the following parameters:

- Write burst mode (SDRC.SDRC\_MR\_p[9] WBST bit (where p = 0 or 1 for SDRC CS0 or CS1)
- CAS latency (SDRC.SDRC\_MR\_p[6:4] CASL field)
- Serial/interleaved mode (SDRC.SDRC\_MR\_p[3] SIL bit)
- Burst length (SDRC.SDRC\_MR\_p[2:0] BL field)

MR is accessible through SDRC.SDRC\_MR\_p (where p = 0 or 1 for SDRC CS0 or CS1). Writing to SDRC.SDRC\_MR\_p initiates an implicit load mode register command qualified by BA1, BA0 = 0, 0.

### 1.2.4.5.2 Extended Mode Register 2 (EMR2)

It is a 12-bit register and controls the following parameters:

- Temperature-compensated self-refresh (SDRC.SDRC\_EMR2\_p[4:3] TCSR field)
- Partial array self-refresh (SDRC.SDRC\_EMR2\_p[2:0] PASR field)

EMR2 is accessible through SDRC.SDRC\_EMR2\_p (where p stands for CS0 or CS1). Writing to SDRC.SDRC\_EMR2\_p initiates an implicit load mode register command qualified by BA1, BA0 = 1, 0.

---

**Note: PASR Setting Before Entering Self-Refresh Mode:**

PASR (Partial Array Self-Refresh) allows memory accesses to all banks when the attached memory is not in self-refresh. The software must ensure that after a self-refresh mode with PASR field enabled on banks, only accesses to the refreshed parts of the memory are performed. Failure to do so may result in fetching corrupted data.

---

## 1.2.5 SDRC Subsystem Basic Programming Model

This section contains programming guides on setting up the SMS and SDRC registers according to the required application.

### 1.2.5.1 SMS Basic Programming Model

#### 1.2.5.1.1 SMS Firewall Usage

Use the SMS.SMS\_SECURITY\_CONTROL register to allow access to the registers.

Because region 0 always has level 0 priority, it can be masked by any protected region.

To configure a region:

1. Set the SMS.SMS\_RG\_ATTi register (where i is the region index from 0 to 7).
2. Set the SMS.SMS\_RG\_RDPERMi register.
3. Set the SMS.SMS\_RG\_WRPERMi register.
4. Set the SMS.SMS\_RG\_STARTj register (except for region 0. j is the region index from 1 to 7).
5. Set the SMS.SMS\_RG\_ENDj register (except for region 0. j is the region index from 1 to 7).

Region 0 is always active. There are no start and an end address for region 0. As soon as the SMS.SMS\_RG\_STARTj[30:16] STARTADDRESS and SMS.SMS\_RG\_ENDj[30:16] ENDADDRESS registers (where j = 1 to 7) are programmed, the firewall is activated. To prevent unexpected violations, ensure that the protection regions do not overlap.

Region 1 ensures the proper dynamic programming of protection for regions 2 through 7. For example, the protected region A is set and currently accessed, but it must be enlarged. To avoid deactivating region A and exposing its content to unwanted leakage, region 1 can be used to mask this whole area during reprogramming. When region A is correctly reprogrammed, region 1 can be deactivated.

If the secure system wants to restrict use of the firewall to secure mode, the security control register allows setting of a bit that locks the access to all registers to secure supervisor only.

On general-purpose (GP) devices, when all the required regions are programmed, the locking mechanism allows freezing the configuration, thus ensuring no further reprogramming.

To program the SMS firewall region in secure and supervisor privilege only, the SMS\_SECURITY\_CONTROL register allows any transaction or only secure and supervisor privilege accesses to:

- Rotation context registers (only secure privilege required)
- Arbitration control registers (only secure privilege required)
- Region 1 security firewall registers
- Error log registers (only secure privilege required)
- Security control register configuration lock bit
- Firewall lock bit
- Soft-reset lock bit (only secure privilege required)

If these fields are programmed to 0x1 (meaning that secure and supervisor privilege transaction is required), then nonsecure and supervisor privilege accesses to corresponding registers do not modify the register values and generate an ERRORSECREG error in the SMS\_ERR\_TYPE register.

#### 1.2.5.1.2 VRFB Context Configuration

Using the RE requires several initialization programming steps. After an RE context is set up, an application can use it transparently, as if addressing a frame buffer object with a standard raster-based memory arrangement.

1. Define the page configuration. This operation usually depends only on the external memory device. The same page settings are then applied to any newly created rotated frame buffer.

Consider an SDRAM device with 1024-byte pages. The page can be defined as a  $16 \times 64$  array. The page is not necessarily a square ( $32 \times 32$  is also a suitable value). It is recommended that the longest side corresponds to the access direction requiring the maximum bandwidth.

In terms of register settings, in any context that uses that page size:

Page (page) width =  $2^{pw}$  bytes (that is,  $pw = 6$ )

Page (page) height =  $2^{ph}$  rows (that is,  $ph = 4$ )

2. The application must allocate the appropriate amount of memory in the SDRAM address space, as required by the size of the frame buffer object.

*Example: Create a  $400 \times 300$  frame buffer, 16 bits per pixel*

- Pixel size =  $2^{ps}$  bytes (that is  $ps = 1$ )
- Number of pages per line:  $400 \times 2/64 = 12.5$ , rounded up to 13
- Number of pages per column:  $300/16 = 18.75$ , rounded up to 19

In terms of register settings, the image size parameters correspond to the enlarged image, and are programmed to:

- Image width =  $w$  pixels (that is,  $w = 13 \times 64 / 2 = 416$ )
- Image height =  $h$  pixels (that is,  $h = 19 \times 16 = 304$ )

---

**Note:** In this example, the values obtained are not integer values, but are rounded up to the closest integer value. This results in a loss of physical memory, generally negligible compared to the total size of the image.

---

In terms of memory allocation (in the physical memory), this corresponds to a  $416 \times 304 \times 2 = 252,928$ -byte buffer.

The physical base address of this buffer must be aligned on a page boundary (in that example, a 1024-byte boundary; that is, the 10 LSBs of the base address must be all zeros). This buffer must be allocated as a contiguous memory segment.

All these parameters, once determined, must be loaded in the registers of the chosen context (there are 12 VRFB contexts with 12 independent sets of registers).

*Example, context 1:*

- Configure the physical base address of the frame buffer. Example: 512 Mbytes, start of CS0, SMS.SMS\_ROT\_PHYSICAL\_BAn[30:0] PHYSICALBA = 0x20000000 (where  $n = 1$ )
  - Configure the image height and width:  
Image width (416): SMS.SMS\_ROT\_SIZEEn[10:0] IMAGEWIDTH = 0x1A0 (where  $n = 1$ )  
Image height (304): SMS.SMS\_ROT\_SIZEEn[26:16] IMAGEHEIGHT = 0x130
  - Configure the control parameters:  
Pixel size (example: 2 bytes,  $2^1$  bytes): SMS.SMS\_ROT\_CONTROLn[1:0] PS = 0x1 (where  $n = 1$ )  
Page (page) size (example: 1024 bytes = 64 bytes  $\times$  16 bytes)  
Page height (example: 16 rows,  $2^4$  rows): SMS.SMS\_ROT\_CONTROLn[10:8] PH = 0x4  
Page width (example: 64 bytes,  $2^6$  bytes): SMS.SMS\_ROT\_CONTROLn[6:4] PW = 0x6
3. The frame buffer just created is now ready for use by the different system initiators (MPU, sDMA, LCD controller, etc.).

From the perspective of these modules, the frame buffer object can be accessed at the following VRFB address-space memory locations:

- Context 1 0-degree view: 0x7400 0000
- Context 1 90-degree view: 0x7500 0000
- Context 1 180-degree view: 0x7600 0000
- Context 1 270-degree view: 0x7700 0000

The start address of the view corresponds to the logical origin of the image ( $x = 0$ ,  $y = 0$ ). The image pitch parameter, commonly defined as the distance between two vertically adjacent pixels, is fixed to 2048 pixels.

*Example of usage by the application:*

In a system using an  $400 \times 300$  LCD panel that has a native landscape orientation, the natural scan order is as shown in [Figure 1-60](#).

**Figure 1-60. Natural Scan Order**

sdrc-018

The display buffer is the one created in the example sequence.

When the application is running and uses the portrait orientation for the display (typically, a PDA-type application):

- The LCD controller accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, use the 90-degree view.

When the application is running and uses the landscape orientation for the display (typically, a video recorder/player or gaming application):

- The LCD controller still accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, also use the 0-degree view. See [Section 1.2.6.1.1](#).

#### 1.2.5.1.3 Memory-Access Scheduler Configuration

The memory-access scheduler is configured as follows:

- Register security settings
  - SMS.SMS\_SECURITY\_CONTROL register
    - Arbitration control registers security level (SMS.SMS\_SECURITY\_CONTROL[5] ARBITRATIONREGSLOCK bit)
- For each of the three classes, the arbitration parameters are:
  - SMS.SMS\_CLASS\_ARBITER0 through SMS.SMS\_CLASS\_ARBITER2
    - One high-priority FIFO queue in the class (HIGHPRIOVECTOR field)
    - Number of consecutive transactions to perform (EXTENDEDGRANT field)
    - Burst transaction submitted for arbitration immediately or after the burst has been buffered (BURST-COMPLETE field)

#### 1.2.5.1.4 Error Logging

All data transfers in the SMS are full handshake. The SMS uses this capability to signal the system when a transaction error is detected.

The SMS captures the address of the faulty access in the SMS.SMS\_ERR\_ADDR register. The error type is logged in the SMS.SMS\_ERR\_TYPE register. Once a faulty access is logged and the SMS.SMS\_ERR\_TYPE[0] ERRORVALID bit is set, the next faulty accesses cannot be logged before clearing the ERRORVALID bit.

In the case of an interconnect transaction, an error response is generated if any of the following occur:

- An incoming request arrives after an idle request from the PRCM.
- An illegal command is received.

- A protection region overlap is detected.
- A nonsecure or non-supervisor write access to the security control register is detected.
- Protection errors.

It is assumed that the system interconnect on which the SMS is plugged is responsible for signaling the error event to the host MPU based on the interconnect response. The MPU error handler can then consult the error logging registers.

The security control register allows locking the SMS.SMS\_ERR\_ADDR and SMS.SMS\_ERR\_TYPE registers to secure- and supervisor-only accesses. This configuration is highly recommended for high-security devices. For GP devices, ErrorLog can remain public.

## 1.2.5.2 SDRC Configuration

### 1.2.5.2.1 Reset Behavior

The reset behavior of the SDRC can be classified into three subgroups:

- Asynchronous cold-reset (power-on reset) behavior
- Asynchronous warm reset behavior
- Synchronous soft-reset behavior

When the system-wide power-on reset is applied through cold reset, all flops are reset to their default values, and all state-machines are returned to their idle states.

The programming model for data recovery following a warm reset is as follows:

- Program the SDRC.SDRC\_POWER\_REG register to enable the SDRC.SDRC\_POWER\_REG[7] SRFONRESET bit.

A warm reset condition is then issued.

- The SDRC enters self-refresh mode since the SRFONRESET bit is set.
- The SDRC does not execute global SDRC reset since the reset is not qualified as cold.
- The SDRC state-machine maintains the external memory device in self-refresh.

The first SDRC access to the configuration register must then be:

1. Check the SDRC configuration.
2. Exit self-refresh mode using the manual command register.

A software-controlled reset is also available by using the SDRC.SDRC\_SYSCONFIG[1] SOFTRESET bit (set this bit to 1 to activate the reset). The completion of the reset can be determined by reading the SDRC.SDRC\_SYSSTATUS[0] RESETDONE bit.

When the SDRC is reset due to the presence of either a soft or cold reset, all SDRC flops are reset.

---

**Note:** **SDRC Requirement at First Power-Up to have sdrc\_cke Pin High.**

To be compliant with JEDEC standard, sdrc\_cke pins values are forced to 1 during the initial memory power-up phase: software must ensure that sdrc\_cke pin is released after the initialization phase; it happens only at first power-up (on a cold reset). Thus, at the end of the initial SDRC power-up sequence and before programming the PWDENA field, software must ensure that sdrc\_cke pin is driven by SDRC module. Then, value of the PWDENA field can be modified. Refer to [Section 1.2.5.4.1](#) for more details on sdrc\_cke driving.

---

## 1.2.5.3 SDRC Setup

A number of device parameters must be set before executing the initialization sequence.

### 1.2.5.3.1 Chip-Select Configuration

Chip-select CS0 always starts at 0x8000 0000 (with respect to the 32-bit interconnect address). There is no restriction on the presence of any SDRAM on either CS0 or CS1.

The total address space of the SDRC is 1 Gbyte / 8 Gbits. The total address space is divided into  $8 \times 128$  Mbytes partitions as shown in [Figure 1-50](#). Each partition is a possible start address for CS1, except for the partition occupied by CS0.

The start address for CS1 is defined by the SDRC.SDRG\_CS\_CFG[9:8] CS1STARTLOW and SDRC.SDRG\_CS\_CFG[3:0] CS1STARTRHIGH fields.

Space 0, selected by the SDRC using the CS0 (nCS0) output pin, is always at offset 0 from the SDRAM memory space base address. The size of this area is programmable through the SDRC.SDRG\_MCFG\_p[17:8] RAMSIZE field, where  $p = 0$ . Space 1, selected by the SDRC using the CS1 (nCS1) output pin, is at an offset from the SDRAM memory space base address; this offset is programmable in 128 Mbytes increments. The size of this area is programmable through the SDRC.SDRG\_MCFG\_p[17:8] RAMSIZE field, where  $p = 1$ . The type of device for each area is programmable through the SDRC.SDRG\_MCFG\_p register (where  $p = 0$  or 1 for SDRC CS0 or CS1).

---

**Note:** Ensure that space 0 and space 1 do not overlap each other or extend farther than the maximum 1 Gbyte SDRC memory space as explained in Global Memory Space Mapping section of the *Memory Mapping* chapter.

---

### 1.2.5.3.2 Memory Configuration

The memory configuration is defined on a per-CS basis through the SDRC.SDRG\_MCFG\_p register (where  $p = 0$  or 1 for SDRC CS0 or CS1).

[Table 1-70](#) lists the memory configuration.

**Table 1-70. Memory Configuration**

Bit Field	Comments
ADDRMUXLEGACY	Address multiplexing scheme
RAMSIZE	Defines the physical RAM address space in terms of 2 Mbytes chunks
B32NOT16	External device data bus width.
DEEPPD	Set this bit if the memory supports deep-power-down mode. (This bit is only a flag for software. It does not affect any SDRC function.)
DDRTYPE	Mobile DDR
RAMTYPE	SDRAM type

---

**Note: Exported Register Reset Values and Lock Bit**

The SDRC.SDRG\_MCFG\_p and SDRC.SDRG\_SHARING reset values are exported in the control module. At reset, these registers take the value previously stored in the control module. A new bit is added to each register to provide the capability to lock these three registers into read-only accesses:

- SDRC.SDRG\_MCFG\_p[30] LOCKSTATUS bit ( $p = 0$  or 1 for CS0 or CS1)
- SDRC.SDRG\_SHARING[30] LOCK bit

The reset value of each lock bit is also imported from the control module.

---

### 1.2.5.3.3 SDRAM AC Timing Parameters

The AC parameters described in [Table 1-71](#) can be independently programmed (standard JEDEC LPDDR1 terminology is used here) in clock cycles for each of the two memory areas through registers SDRC.SDRG\_ACTIM\_CTRLA\_p and SDRC.SDRG\_ACTIM\_CTRLB\_p ( $p = 0$  or 1, depending on the CS area).

**Table 1-71. Programmable AC Parameters**

SDRC AC Parameter	Description	Range (Clock Ticks)
tRFC	AUTO REFRESH to ACTIVE / AUTO REFRESH command period (autoReFresh Cycle time)	0 - 31
tRC	ACTIVE to ACTIVE command period (Row Cycle time)	0 - 31
tRAS	ACTIVE to PRECHARGE command period	0 - 15
tRP	PRECHARGE command period (Row Precharge time)	0 - 7
tRCD	ACTIVE to READ or WRITE delay (Row-to-Column Delay time)	0 - 7
tRRD	ACTIVE bank A to ACTIVE bank B delay	0 - 7
tWR	WRITE Recovery time (also known as tDPL)	0 - 7
tDAL	Auto precharge write recovery + precharge time	0 - 31
tWTR	Internal Write to Read command delay (also known as tCDLR)	0 - 7
tCKE	CKE min pulse width (high and low pulse width)	0 - 7
tXP	Exit Power-Down to next valid command delay	0 - 7
tXSR	Self-Refresh exit to next valid command delay	0 - 255

Example of configuration:

If there is a minimum tRC requirement of 88 ns at 100 MHz,  $88/10 = 9$  (8.8 is rounded up).

Therefore, nine clock cycles must be set.

The SDRC AC parameters described in [Table 1-72](#) are hard-coded.

**Table 1-72. Nonprogrammable AC Parameters**

SDRC AC Parameter	Description	Range (Clock Ticks)	Comment
tMRD	MODE REGISTER SET command period	3	
tDQSS	Write command to first DQS latching transition	1 (0.75 - 1.25 CK)	
tRPRE	Read preamble	1 (0.9 - 1.1 CK)	DQS is held low for read when driving on the same cycle as the read command is stopped.

**Note:** The SDRC uses tXSR only when exiting self-refresh mode, regardless of the first command issued. The SDRC systematically inserts an autorefresh command before it serves the first request.

#### 1.2.5.3.4 DLL/CDL Configuration

The DLL unit is configured by writing to the SDRC.SDRC\_DLLA\_CTRL register. This register contains the following fields:

- FIXEDDELAY
- MODEFIXEDDELAYINITLAT
- WRITEDDRCLKX2DIS
- DLLMODEONIDLEREQ
- DLLIDLE
- ENADLL
- LOCKDLL
- DLLPHASE

**Note:** OMAP3430 DLL/DCDL usage (SWPA119) describes the use of DLL/CDL in the OMAP3430 device. For further information about this application note contact a Texas Instruments representative.

To support low-frequency DDR access, set the DLL in Fixed Delay mode by setting the SDRD\_DLLA\_CTRL [2] LOCKDLL bit to 0x1. In this mode, the SDRD\_DLLA\_CTRL [31:24] FIXEDDELAY field allows the programming of the CDL delay. This provides the correct fixed DCB code based on the input frequency. Only the voltage precharge part of the DLL is still used to control the CDL instances in this mode, but the control loop is broken and the voltage control is inactive.

When fixed delay mode is enabled, a counter (programmable through the SDRD\_DLLA\_CTRL [23:16]MODEFIXEDDELAYINITLAT field) based on the input frequency allows the SDRC to stall all incoming requests. Once this counter expires, the SDRC starts accessing the memory. The DLL characterization has showed that this feature is not useful and that this value shall be set to 0x0, leading actually a null delay.

WRITEDDRCLKX2DIS controls which clock is used for the write data path. The WRITEDDRCLKX2DIS bit ensures the proper MDDR write data bytes by using a double frequency input clock coming from the PRCM module.

The DLL can be put in idle mode using the SDRD\_DLLA\_CTRL[4] DLLIDLE bit. When in idle mode, the DLL lock is lost. The precharge voltage is kept stable to enable faster relock when going back to a functional state. If set, this bit overrides the ENADLL bit. Thus, avoid completely powering down the DLL by keeping the precharge voltage and cutting off the analog loop. Exiting from this idle mode saves some clock cycles compared to exiting from power-down mode. Refer to the note (DLL behavior upon a warm reset assertion) in [Section 1.2.4.4.9.2, Dynamic Low-Power Operating Modes](#). Furthermore, the SDRD\_DLLA\_CTRL[6:5] DLLMODEONIDLEREQ field defines the modes (Power-Down / DLLIDLE / No action) of the DLL that are automatically entered upon an Idle\_req assertion. The DLL mode (TrackedDelay or ModeFixedDelay mode) is updated only when Idle\_req/Idle\_ack handshake protocol occurs, warm reset occurs, PWRDN is enabled, or DLLIDLE mode enabled. Power-Down mode is asserted upon warm reset assertion. If power-down and DLLIDLE are asserted simultaneously, power-down overwrites DLLIDLE mode inside the DLLCDL cell.

To modify the SDRC input clock when the DLL is locked and active, the DLL must first enter either its idle mode or its power-down mode. The SDRC input frequency can be changed by using any of the following scenarios:

- Internal signals handshaking protocol with PRCM module
- Warm reset event
- DLLIDLE mode
- Power-Down mode

The ENADLL bit controls the PWRDN mode of the DLL module.

The LOCKDLL bit sets the DLL in TrackedDelay (lock) or ModeFixedDelay (unlock) mode. ModeFixedDelay mode is supported up to 83MHz.

The DLLPHASE control bit is used to set up the nominal delay tracked by the DLL. It is recommended for read accesses to use 72 degrees and for write accesses 90 degrees without DLL/DCDL. See [Section 1.2.4.4.11](#) for more information on the CDL/DLL module.

DLLMODEONIDLEREQ is of no importance to the Idle\_ack generation. In case DLLMODEONIDLEREQ = 2 and Idle\_req occurs, Idle\_ack can be generated and SDRC/core can go to idle; however, recovery from this state may be incorrectly performed and the DLL cannot relock. If this happens, the only solution to recover is to disable and then re-enable the DLL. DLLMODEONIDLEREQ = 2 is not a valid configuration under Idle\_req assertion and must not be used. DLLMODEONIDLEREQ can be set 0 or 1, depending on whether the priority is shorter wake-up latency or lower power consumption.

### 1.2.5.3.5 Mode Register Programming and Modes of Operation

The SDRC contains a group of registers known as the Memory Mode Registers. These registers define the operational modes of the target SDRAM.

- MR: Mode Register used to define operational parameters.

- EMR1: Extended Mode used to define operational parameters exclusive to DDR SDRAM (irrelevant to the SDRC since regular DDRs are not supported).
- EMR2: Extended Mode used to define operational parameters exclusive to mobile SDRAM.

#### 1.2.5.3.5.1 Mode Register (MR)

The 12-bit SDRC.SDRC\_MR\_p register (p = 0 or 1 for CS0 or CS1) controls the following parameters:

- Write burst mode
- CAS latency
- Serial/interleaved mode
- Burst length

When programming the SDRC.SDRC\_MR\_p bit fields (where p = 0 or 1 for SDRC CS0 or CS1), consider the following:

- CAS latencies of 1, 2, 3, 4, and 5 are supported (CASL).
- Only serial mode (not interleaved mode) is supported (SIL = 0x0).
- A burst length of 4 is supported for DDR SDRAM (BL = 0x4).
- Burst lengths of 1 (BL = 0x0), 8 (BL = 0x3), and full page (BL = 0x7) are not supported.

Writing to SDRC.SDRC\_MR\_p initiates an implicit Load Mode register command qualified by BA1,BA0 = 0,0 except if the NOMEMORYMRS bit is set.

#### 1.2.5.3.5.2 Extended Mode Register 2 (EMR2)

The SDRC.SDRC\_EMR2\_p register (p = 0 or 1 for CS0 or CS1) is specific to mobile SDRAM devices. It is a 12-bit register that controls the following standard parameters:

- Partial Array Self-Refresh (PASR)
- Temperature Compensated Self-Refresh (TCSR)
- Driver Strength (DS)

The SDRC.SDRC\_EMR2\_p[2:0] PASR field programs the partial array self-refresh feature. The SDRC.SDRC\_EMR2\_p[4:3] TCSR field programs the temperature compensated self-refresh feature.

Writing to SDRC.SDRC\_EMR2\_p initiates an implicit load mode register command qualified by BA1, BA0 = 1,0 except if SDRC\_SYSCONFIG[8] NOMEMORYMRS is set.

#### 1.2.5.3.6 Autorefresh Management

The SDRAM refresh configuration register group controls refresh management in normal operation. This group contains two SDRC.SDRC\_RFR\_CTRL\_p registers that are defined on a per-CS basis and contain the following bit fields:

- SDRC.SDRC\_RFR\_CTRL\_p[1:0] ARE (where 'p' stands for SDRC CS values 0 and 1)
- SDRC.SDRC\_RFR\_CTRL\_p[23:8] ARCV (where 'p' stands for SDRC CS values 0 and 1)

These bit fields can enable and disable autorefresh. Autorefresh bursts of 1, 4, and 8 are programmed using these fields. The autorefresh burst starts when the 16-bit autorefresh counter decrements to 0. The ARCV field loads the autorefresh counter with a 16-bit autorefresh value. The ARCV value is calculated using the following formula:

$$\text{Refresh value} = (\text{refresh interval} / \text{clock period} / \text{number of rows}) - \text{margin}$$

**Note:** Memory refresh interval in time unit. Margin is 50 (cycles).

The margin considers the possibility of an ongoing access when the counter expires, thus delaying the effective refresh sequence.

The value to be programmed is independent of the burst-refresh configuration: if a burst-refresh is configured, the value is automatically scaled in hardware to the burst-refresh size.

Autorefresh is enabled by programming the SDRG.SDRG\_MANUAL\_p[3:0] CMDCODE field to 0x2 (where p = 0 or 1 for SDRG CS0 or CS1).

#### 1.2.5.3.7 Page Closure Strategy

The page closure strategy is defined on a per-bank basis by setting the SDRG.SDRG\_POWER\_REG[0] PAGEPOLICY bit. SDRG defines one type of page closure strategy:

1. High power/high bandwidth: Bandwidth consumption is critical.

The SDRG tracks open pages. The SDRG determines whether the current access is an open page or a closed page. The SDRG does the following:

1. If the current page is already open on this bank the SDRG automatically issues a *precharge* command to close that bank.
2. Opens the accessed page
3. Executes the access

In the worst case, four pages (one page per bank) may be opened simultaneously.

The PAGEPOLICY bit must be set to 1 to enable this mode.

#### 1.2.5.4 Manual Software Commands

The manual commands register SDRG.SDRG\_MANUAL\_p (where p = 0 or 1 for SDRG CS0 or CS1) is used to implement software-driven commands:

- NOP command
- Precharge All command
- Autorefresh command
- Enter deep-power-down command
- Exit deep-power-down command
- Enter self-refresh command
- Exit self-refresh command
- Set CKE high command
- Set CKE low command

These commands are described in the following section:

- NOP (CMDCODE: 0x0)

When the SDRG.SDRG\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x0, the SDRG issues a NOP/inhibit command. The following table lists the status of the SDRG memory port signals.

NOP does not initiate any new operation, but it is needed to complete operations that require more than a single clock cycle-like autorefresh.

Inhibit is also a NOP. nCS high disables the command decoder so that nRAS, nCAS, nWE, and all the address inputs are ignored.

Command	nCS	nRAS	nCAS	nWE
Inhibit	H	X	X	X
NOP	0	H	H	H

- Precharge all (CMDCODE: 0x1)  
When the SDRC.SDRG\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x1, the SDRC issues a precharge all command. The following table lists the status of the SDRC memory port signals. During the command, address A10 remains high, and bank information (BA0 and BA1) is don't care. All banks can be precharged at the same time by using the precharge all command. At the end of tRP, after performing precharge on all of the banks, they enter the idle state.

Command	A10	nCS	nRAS	nCAS	nWE
Precharge all	H	L	L	H	L

- Autorefresh (CMDCODE: 0x2)  
When the SDRC.SDRG\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x2, the SDRC issues an autorefresh command. The following table lists the status of the SDRC memory port signals. In addition to the signal status mentioned below, the CKE signal is at logic high for autorefresh. The autorefresh command can only be asserted when all banks are in idle state and the device is not in power-down mode (CKE is high in the previous cycle). The autorefresh command must be followed by NOPs until the autorefresh operation completes. All banks are in the idle state at the end of the autorefresh operation.

Command	nCS	nRAS	nCAS	nWE
Autorefresh	L	L	L	H

- Enter deep-power-down (CMDCODE: 0x3)  
When the SDRC.SDRG\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x3, the SDRC executes an enter DPDM command. This command is used for low-power devices (that is, MDDR devices that support deep-power-down mode). The following table shows the status of the SDRC memory port signals. The device enters deep-power-down mode by having nCS and nWE held at logic low with nRAS and nCAS high at the rising edge of the clock, while CKE is low.

Command	nCS	nRAS	nCAS	nWE	CKE
Enter DPDM	L	H	H	L	L

- Exit deep-power-down command (CMDCODE: 0x4)  
When the SDRC.SDRG\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x4, the SDRC executes an exit deep-power-down command. The device exits deep-power-down mode when the inhibit command is sampled with CKE held at logic high.
- Enter self-refresh (CMDCODE: 0x5)  
When the SDRC.SDRG\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x5, the SDRC puts the memory into self-refresh. The signal status is the same as defined in autorefresh, and CKE is held at logic low during the self-refresh entry command. The self-refresh mode is entered from the all-banks-idle state by asserting nCS, nRAS, nCAS, and CKE low, and nWE high. Once the self-refresh mode is entered, only the CKE state being low matters; all other inputs, including the clock, are ignored and remain in self-refresh mode.
- Exit self-refresh (CMDCODE: 0x6)  
When the SDRC.SDRG\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x6, the SDRC executes the self-refresh exit command and, after meeting the tXSR timing parameter, executes one autorefresh command to adhere to the memory protocol. It is an exit self-refresh command when CKE is detected high with a NOP command. Self-refresh is exited by restarting the external clock and then asserting CKE high. This must be followed by NOPs for a minimum time of tXSR before the SDRAM reaches idle state to begin normal operation.
- Set the CKE signal high (CMDCODE: 0x7)

When the SDRC.SDRC\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x7, CKE is set to high. An example of where this command is used is during DDR memory initialization.

- Set the CKE signal low (CMDCODE: 0x8)

When the SDRC.SDRC\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x8, CKE is set to low. An example of where this command can be used is to put memory in power-down mode.

#### 1.2.5.4.1 DDR Initialization Sequence

The initialization sequence is executed after the following occur:

1. Power is applied.
2. The clock is stable.
3. The power-on reset sequence is executed.

The initialization sequence is executed by programming the following manual command registers, in the SDRC.SDRC\_MANUAL\_p[3:0] CMDCODE bit field, on a per-CS basis:

1. Set CMDCODE to 0x0 (NOP command), for a minimum delay of 200  $\mu$ s. Another way to stabilize the connected device internal circuits is to deactivate the corresponding CS for the same amount of time.

#### CAUTION

It is the programmer's responsibility to ensure that the next command (precharge all command) is sent after a minimum delay of 200  $\mu$ s. Other timings to respect, such as tRP timing between precharge all command and autorefresh command are automatically handled by the SDRC controller depending on the timing values programmed in the adequate registers.

2. Set CMDCODE to 0x1 (precharge all command) to precharge all banks.
3. Set CMDCODE to 0x2 (autorefresh command). The autorefresh command is automatically generated after a time of tRP, hence SDRC\_ACTIM\_CTRLA\_p[17:15] TRP (where p = 0 or 1, for CS0 or CS1) must be programmed as stated in the external memory datasheet.
4. A second autorefresh command must be programmed. Set CMDCODE to 0x2 another time.
5. Then configure the mode register SDRC\_MR\_p (p = 0 or 1) with BA0 and BA1 set to 0.

Because the mode register powers up in an unknown state, it must be loaded before applying any operational command.

When MR is reprogrammed, a suitable time must elapse before an active command is issued. The hardware ensures this by fixing tMRD to two clock cycles. The SDRC can handle CKE as force on CKE is released through the control module.

After VDD initialization sdrc\_cke0 and sdrc\_cke1 signals are forced outside the SDRC subsystem by the control module. When the external SDRAM device is correctly initialized the control module must release the force on these sdrc\_cke signals by clearing the corresponding MUXMODE bit fields in CONTROL.CONTROL\_PADCONF\_SAD2D\_SBUSFLAG[18:16] and CONTROL.CONTROL\_PADCONF\_SDRC\_CKE1[2:0] bit fields for sdrc\_cke0 and sdrc\_cke1 respectively. See [Section 1.2.5.2.1](#) for more information on reset behavior.

#### 1.2.5.4.2 Read/Write Access

The commands required for a normal read/write access are automatically generated as a function of the following:

- The read/write command
- The address bus. A10 defines precharge all
- The relevant SDRC\_MR\_p / SDRC\_EM2\_p registers

### 1.2.5.4.3 Memory Power Management

#### 1.2.5.4.3.1 Clock Enable Management

The SDRC supports two autonomous clock enable pins CKE0 and CKE1. Each CS (CS0 or CS1) has its own CKE signal. Power management of the CS0 memory is controlled by CKE0. Power management of the CS1 memory is controlled by CKE1. This allows the SDRAM memories associated with CS0 or CS1 to be independently placed in power-down, deep-power-down (DPD) or self-refresh (SR) mode. This is achieved using the manual control register `SDRC.SDRC_MANUAL_p[3:0]` CMDCODE field which is defined on a per chip select basis. Entry and exit of these low-power modes is achieved using the relevant CMDCODE.

Once the memory associated with a CS has been powered down in deep-power-down mode it cannot be powered up by dynamic power management features. It can only exit the low-power state through the programming of the relevant CMDCODE. The SDRC can automatically exit other low-power modes.

#### 1.2.5.4.3.2 Clock-Controlled Memory Power Management

The SDRC power-management register (`SDRC.SDRC_POWER_REG`) contains the `EXTCLKDIS` field, which controls suspension of the external clock on a per-CS basis. Writing 1 to this field in the relevant register freezes the clock with a latency dependent on the `SDRC.SDRC_POWER_REG` register programming. Subsequently, writing 0 to this field in the relevant register enables the clock with a latency dependent on the `SDRC.SDRC_POWER_REG` register programming.

#### 1.2.5.4.3.3 Manual Power-Down Mode Power Management

For a DDR, the sequence is as follows:

##### DDR Mechanism/Power-Down Mode Entry

1. Ensure that no access is currently pending or active.
2. To reduce power consumption (not mandatory): disable DLL by setting the `ENADLL` field of the relevant `SDRC.SDRC_DLLA_CTRL` register to 0x0.
3. Program the CMDCODE field of the relevant manual command register to 0001. This ensures that all banks are idle by executing a precharge all command.
4. Program the CMDCODE field of the relevant manual command register to 0000. This executes a NOP command.
5. Program the CMDCODE field of the relevant manual command register to 1000. This sets the relevant CKE low.
6. Maintain the clock at a stable value.

##### DDR Mechanism/Power-Down Mode Exit

1. Provide clock.
2. Program the CMDCODE field of the relevant manual command register to 0111. This sets the relevant CKE high.
3. Program the CMDCODE field of the relevant manual command register to 0000. This executes a NOP command.
4. Program the CMDCODE field of the relevant manual command register to 0001. This ensures that all banks are idle by executing a precharge all command.
5. Enable DLL by setting the `ENADLL` field of the relevant `SDRC.SDRC_DLLA_CTRL` register to 0x1.

The amount of time the SDRC spends in power-down mode must not exceed the refresh period; otherwise, data becomes corrupted.

#### 1.2.5.4.3.4 Deep-Power-Down Mode Power Management

When in deep-power-down mode the power distribution to the entire memory array is cut. The programming model for deep-power-down mode is as follows:

##### Deep-Power-Down Mode Entry

- Precharge all banks (CMDCODE: 0x1). This ensures that all banks are idle.
- Enter deep-power-down mode (CMDCODE: 0x3).

### Deep-Power-Down Mode Exit

- Exit deep-power-down mode (CMDCODE: 0x4).

The MR and EMR values are retained upon exiting deep-power-down mode.

---

**Note:** Because power-down entry/exit sequences depend on memory devices, see the memory specification for the complete sequence.

---

### 1.2.5.4.3.5 Manual Self-Refresh Mode Power Management

The programming model for entering and exiting self-refresh mode is as follows:

#### Self-Refresh Entry

- Precharge all banks (CMDCODE: 0x1).
- NOP (CMDCODE: 0x0)
- Enter self-refresh mode (CMDCODE: 0x5).

There is no need for the software to disable the autorefresh in the SDRC.SDRC\_RFR\_CTRL\_p register before entering self-refresh. The autorefresh counter is reset in hardware so that an autorefresh cycle is automatically generated immediately after a self-refresh exit, and before any other command.

#### Self-Refresh Exit

- Exit self-refresh mode (CMDCODE: 0x6).
- If needed, reconfigure SDRC registers as required.
- Enable autorefresh by programming:
  - The relevant SDRC.SDRC\_RFR\_CTRL\_p[23:8] ARCV field
  - The relevant SDRC.SDRC\_RFR\_CTRL\_p[1:0] ARE field to the desired refresh burst

### 1.2.5.5 Error Management

All data transfers in the SDRC operate a system of full handshaking. A valid read or write request that is presented to the SDRC by the L3 interconnect sequencer results in the SDRC acknowledging the transfer by raising the SCmdAccept flag. Failure to do this within a defined temporal window constitutes an error. Errors can arise from the following sources:

- Any transaction while the memory is in deep-power-down mode
- An illegal initiator access. The address of the last illegal access is captured in the SDRC.SDRC\_ERR\_ADDR register

If an error occurs, the software error handler performs the following actions:

- Interrogates the ERRORVALID field of the SDRC.SDRC\_ERR\_TYPE register to verify the presence of an error
- Interrogates the ERRORDPD field of the SDRC.SDRC\_ERR\_TYPE register to determine whether a transaction error resulting from the device being in deep-power-down mode is present
- Interrogates the ERRORCONNID field of the SDRC.SDRC\_ERR\_TYPE register to determine whether a transaction error resulting from an illegal access by an interconnect initiator is present
- Interrogates the ERRORADD field of the SDRC.SDRC\_ERR\_TYPE register to determine whether a transaction error resulting from an illegal address is present:
  - Interconnect access to an address outside the memory space (0x0)
  - Interconnect access to an address outside the register space (0x1)
- Writes 0 to the ERRORVALID field of the SDRC.SDRC\_ERR\_TYPE register to clear the active error status
- Executes error recovery from software

## 1.2.6 SDRC Use Cases and Tips

### 1.2.6.1 How to Program the VRFB

#### 1.2.6.1.1 VRFB Rotation Mechanism

An inherent limitation of SDRAM technology is high-memory latency caused by page-miss penalties incurred when downloading to a memory cache. For example, switching from one page to another in external memory can cause a page-miss, indicating that the page accessed for the current pixel is different from that for the previous pixel.

A DMA engine is used to rotate pictures in external DRAM, but this rotation method increases the number of page misses.

The efficient way to rotate image data in external SDRAM is to use the VRFB module, which is an RE embedded in the SMS of the OMAP Applications Processor, as shown in [Figure 1-61](#). It is configured in the SMS registers.

Accessing images stored in external SDRAM in a non-natural order requires an address transaction: the virtual address of an image is translated into a physical address in the corresponding buffer. Address translation causes an image to be rotated in 0-, 90-, 180-, or 270-degree views. With multiple views of the image, the RE can change addresses and issue multiple requests to the SDRC so that a maximum of consecutive accesses is performed, thus decreasing the number of page-miss penalties. The RE cannot reorder requests to the SDRAM.

A VRFB context defines the configuration used to access a picture in external SDRAM. For each VRFB context, a set of registers in the SMS describes:

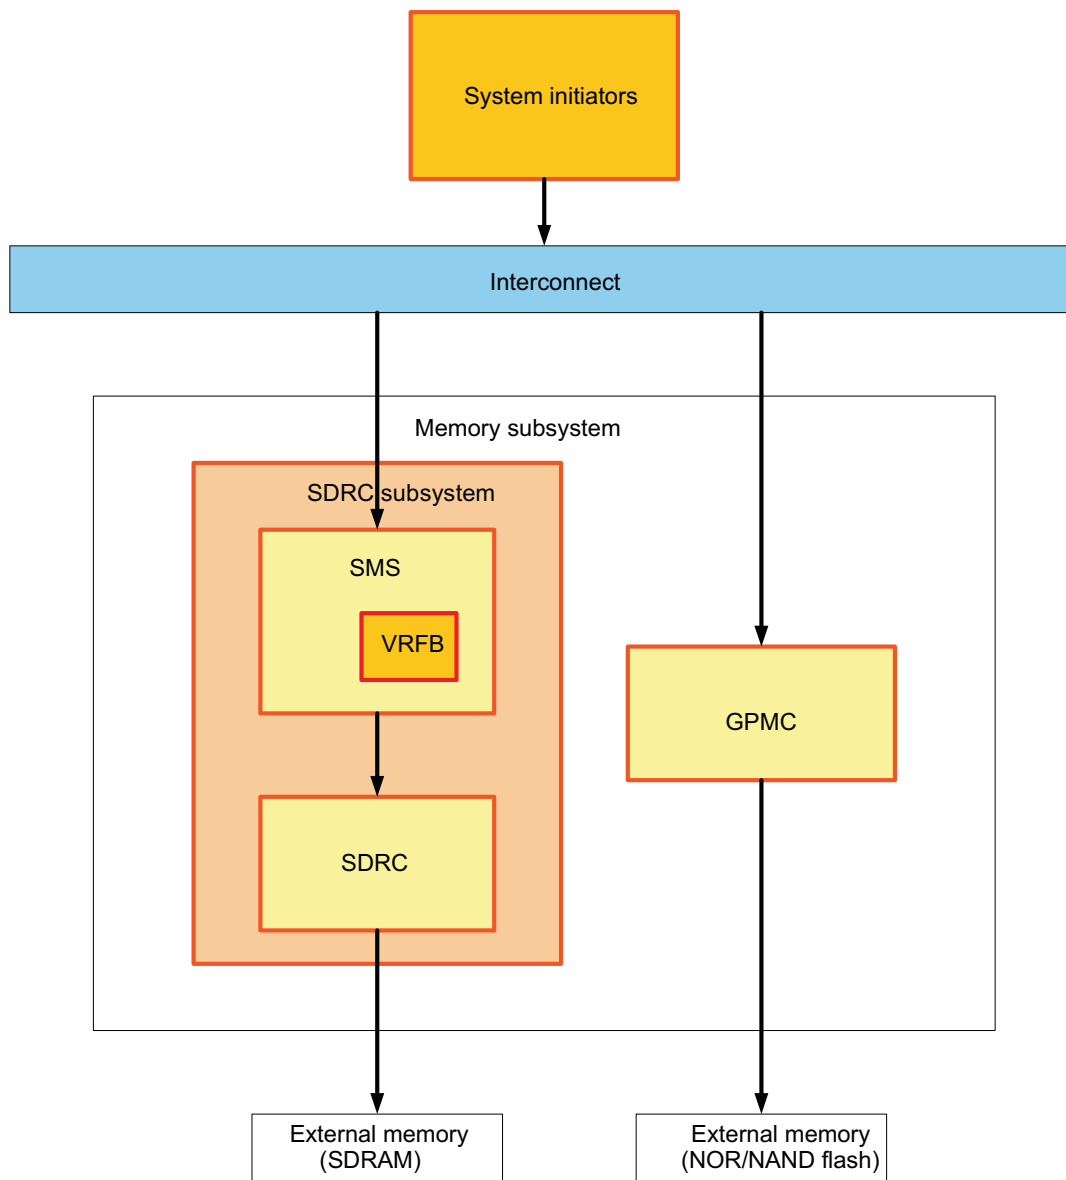

- The size of the page (height and width)
- The picture parameters before rotation (width, height, and pixel format)
- The rotation angle (0-, 90-, 180-, or 270-degree)
- The physical base address in external memory

Any initiator in the OMAP Applications Processor can access up to 12 images simultaneously, each image having an independent context. These 12 contexts is considered virtually addressed image buffers. Each context is assigned to a physical image buffer.

The virtual address space of each context is subdivided into four separate address regions pointing to the same physical image buffer but corresponding to the four possible rotations: 0/90/180/270.

After the VRFB context is configured, all data accesses to an address space are automatically translated when accessing SDRAM through the RE.

Figure 1-61. SDRC Subsystem Overview

sdrc-019

### 1.2.6.1.2 Setting a VRFB Context

**Note: YUV Format**

The YUV standard shows a color space with three elements:

- Y for luminance
- U for chrominance
- V for chrominance

As shown in [Figure 1-62](#), pixel format (not pixel size) used in the YUV standard is spread onto a 32-bit data structure:

- This 32-bit data structure represents a packet of two pixels: P0 and P1.
- Each element (Y0, Y1, U, and V) is coded in 8 bits.
- P0 = Y0; U, V, and P1 = Y1, U, V.

There are 24 bits of information per pixel (Y, U, and V); however, because the chrominance elements U and V are common to both P0 and P1 pixels, only 16 bits are used to store a pixel in YUV format. The YUV standard uses a 32-bit data structure to represent 2 pixels; the pixel format uses 32 bits (4 bytes).

Thus, when defining YUV image parameters, the image width must be set to one-half the number of pixels per row and the pixel format must be set to 4 bytes, because the YUV pixel data is spread onto a 32-bit word representing 2 pixels.

[Figure 1-62](#) shows the pixel representation of the YUV format.

**Figure 1-62. YUV Format: Pixel Representation**

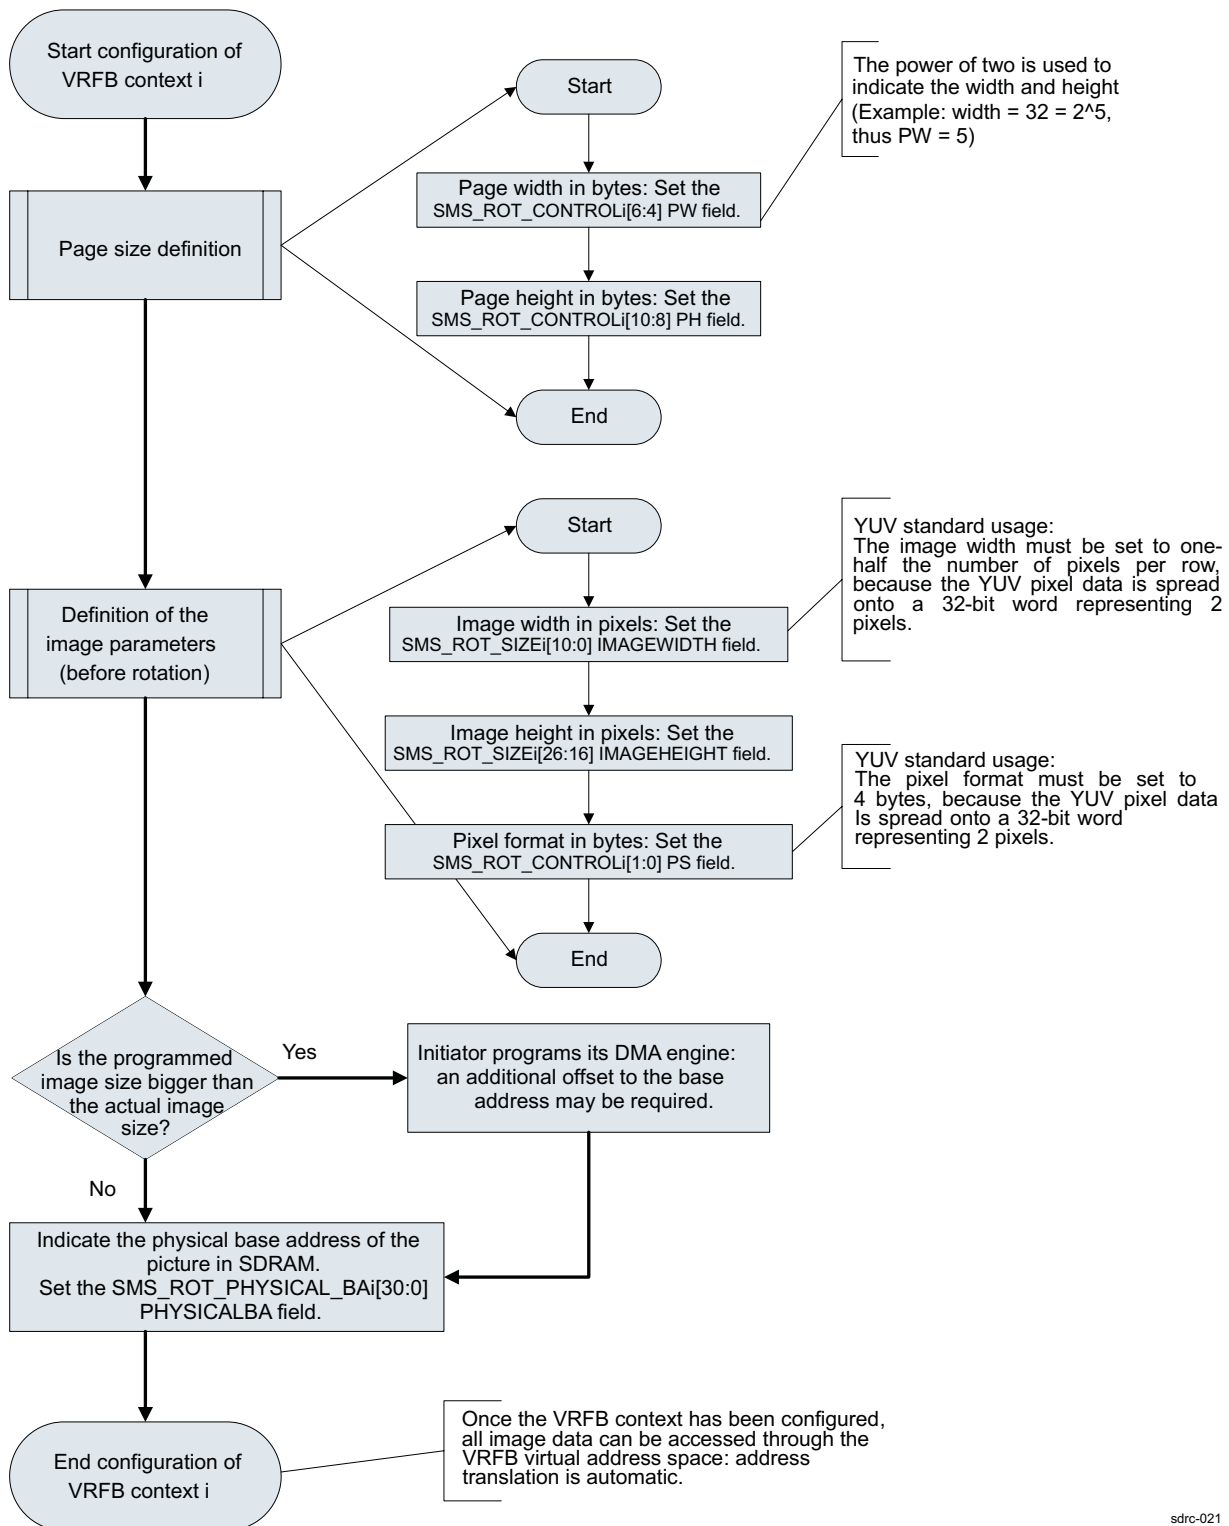

Figure 1-63 shows a generic way to configure a VRFB context to perform a rotation view on pixel data in external DRAM.

Figure 1-63. VRFB Context Configuration

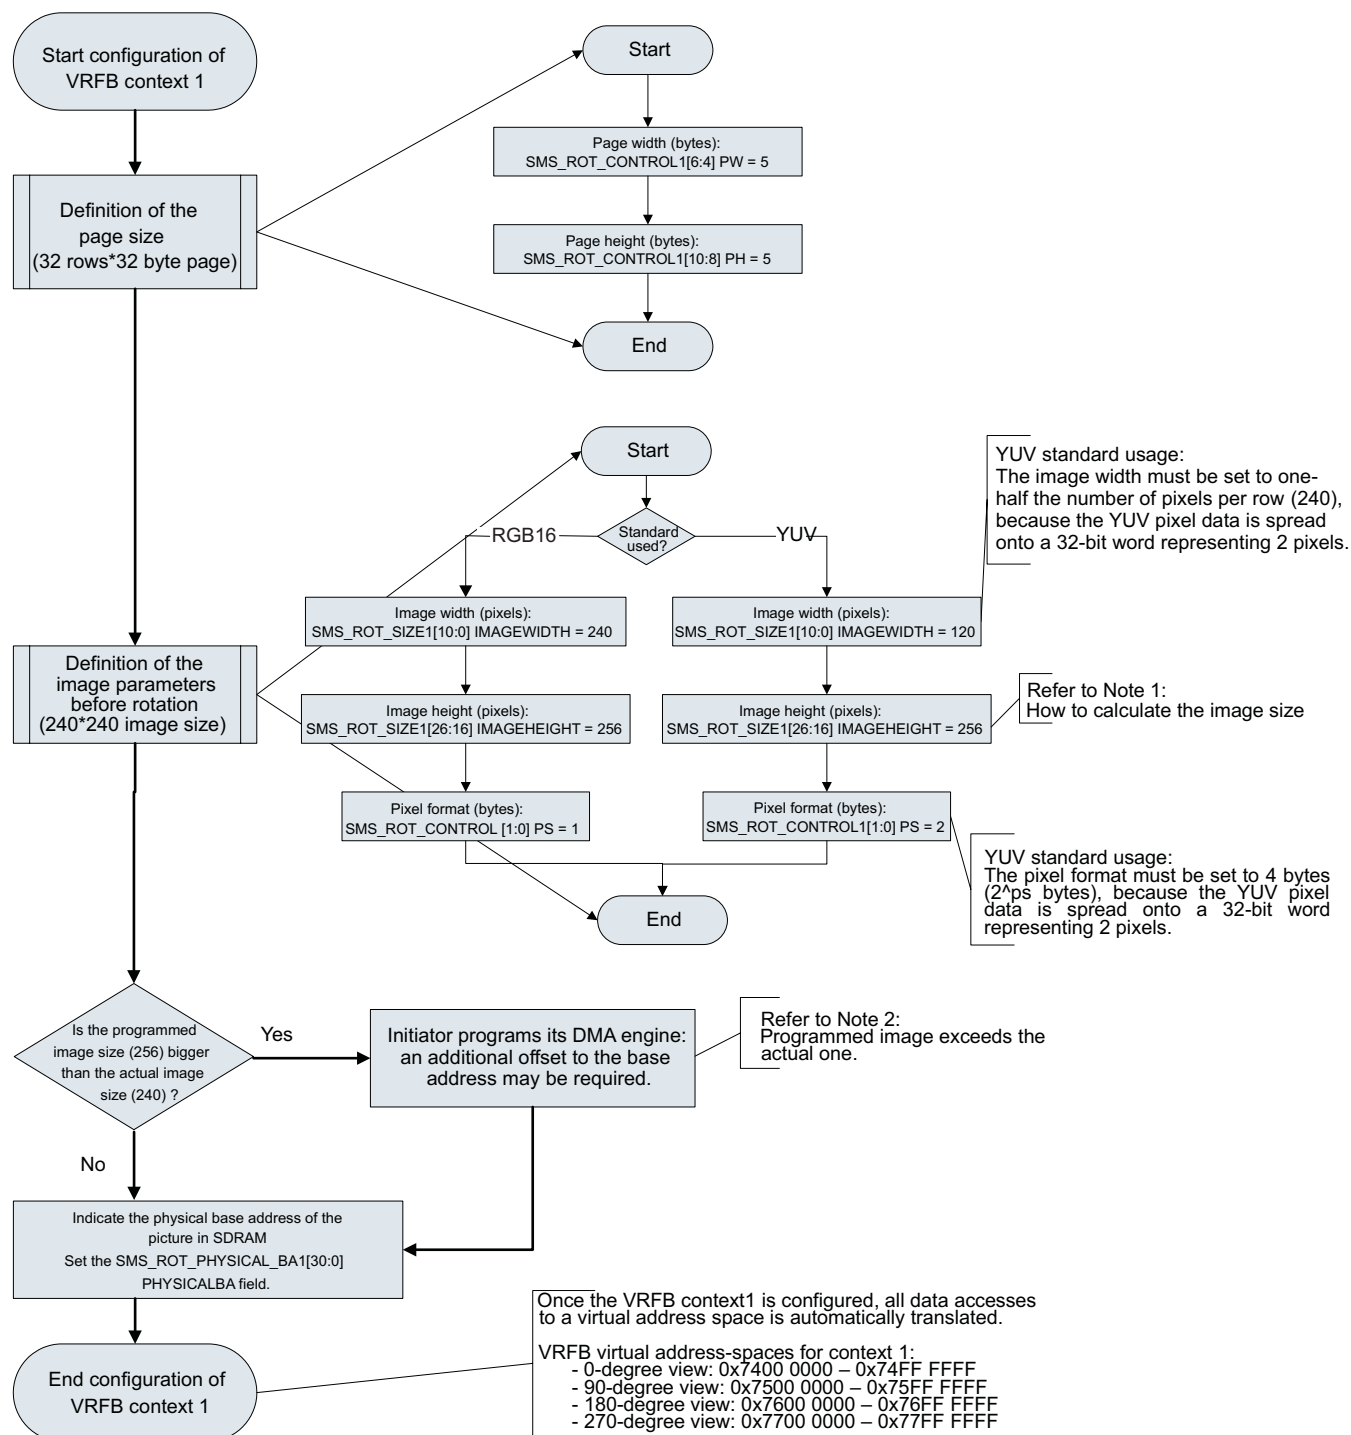

sdrc-021

Figure 1-64 is an example of VRFB context configuration using both RGB and YUV image formats. This example represents the configuration of a 1024-byte page size (32 × 32 byte page) and a 240 × 240 image size using VRFB context 1.

Figure 1-64. Example of VRFB Context 1 Configuration

sdrc-022

Table 1-73 lists guidelines for calculating image size.

**Table 1-73. Calculating Image Size<sup>(1)(2)</sup>**

Steps		RGB16 Format (16-bit Pixel Format)		YUV Format (32-bit Pixel Format)	
		IMAGEWIDTH	IMAGEHEIGHT	IMAGEWIDTH	IMAGEHEIGHT
1	Calculate the required number of pages per line and per column.	240 pixels/32 bytes × 2 bytes per pixel = 15 pages per line	240/32 rows = 7.5, rounded to 8 pages per column	120 pixels/32 bytes × 4 bytes per pixel format = 15	240/32 rows = 7.5, rounded to 8
2	Using the number of pages calculated in Step 1, calculate the image size in pixels.	15 × 32 bytes/2 bytes per pixel = 240	8 × 32 rows = 256	15 × 32 bytes/4 bytes per pixel format = 120	256

(1) Working on a page basis, the image size must be a multiple of the page size.

(2) Depending on the page dimensions and the image size, the programmed image size (256) is larger than the actual image size (240).

To use VRFB rotation, each initiator must configure its DMA engine correctly; an additional offset to the base address may be required. For details, see the *Display Subsystem* chapter.

### 1.2.6.1.3 Applicative Use Case and Tips

#### **Use Case Scenario: Display a Rotated QVGA Image**

Figure 1-65 this use case. The camera captures an image with a particular rotation and stores the pixel data in external memory. Displaying the image on the LCD requires different orientation.

The following components interact while displaying the rotated image:

- SDRC subsystem
- Camera subsystem
- Display subsystem
- External DDR
- VRFB

**Figure 1-65. Display a Rotated QVGA Image**

sdr-023

The following conditions exist for this application:

- QVGA image size is  $320 \times 240$  (width  $\times$  height).
- Pixel format is YUV4:2:2 (YUV2) in little endian.
- The rotation view is 90 degrees.
- The VRFB context is VRFB context 1.
- The camera module writes QVGA images to external DRAM at 15 fps.
- The display subsystem reads QVGA images from external DDR32 at 60 fps and displays them on the LCD screen.
- Read and write initiators use burst mode:
  - The camera uses  $8 \times 64$ -bit burst size.
  - The display uses  $8 \times 32$ -bit burst size.
  - Double-indexing mode is selected.
- The physical address of the buffer in external memory is 0x8030 0000.
- The memory allocation for the buffer is  $320 \times 240 \times 16$ -bit (or  $160 \times 240 \times 32$ -bit).
- The camera subsystem uses its dedicated DMA channel 0.

- The display subsystem uses its video channel 1.

### **Configuring the VRFB through the SMS Registers**

The size of the page supported by the DDR32 memory is 1K byte, which is arranged as 32 × 32 bytes page (width × height).

Configuring the page size:

- SMS\_ROT\_CONTROL<sub>n</sub>[6:4] PW = 5 (where n = 1)
- SMS\_ROT\_CONTROL<sub>n</sub>[10:8] PH = 5

Configuring the image parameters:

- SMS\_ROT\_SIZE<sub>n</sub>[10:0] IMAGEWIDTH = 160 (where n = 1)
- SMS\_ROT\_SIZE<sub>n</sub>[26:16] IMAGEHEIGHT = 256
- SMS\_ROT\_CONTROL<sub>n</sub>[1:0] PS = 2

Physical base address and rotation angle:

- SMS\_ROT\_PHYSICAL\_BA<sub>n</sub>[30:0] PHYSICALBA = 0x8030 0000 (where n = 1).

The image data is accessed at the following virtual address range for 90-degree rotation: 0x7500 0000 – 0x75FF FFFF.

#### **CAUTION**

Image rotation using the YUV2 image format causes the stream to become untidy. The display must be specifically configured to read and reorganize the stream to conform to the YUV2 standard.

### **Tips for Configuring Successful Rotation**

The following guidelines ensure optimal image rotation:

- Page arrangement:  
Usually, the recommendation is to have a *square* page. If this is not possible, the longest page side should correspond to the access direction that requires the maximum bandwidth; set the longest page side to optimize the page break.  
Using a 1024-byte page size, a 32 × 32-byte page arrangement is used as an example. With a 2K-byte page organized as a 32 × 64 byte page, depending on the read or write operation, set the longest page size to optimize the page break. If 0 is written and the 270-degree view is read, page height is greater than page width (PH > PW). Set PH to 64 bytes (PH = 6).
- Virtual address memory arrangement:  
When accessing image data through virtual addresses, the maximum line size supported by the VRFB is 2,048 pixels.  
In the memory buffer, the distance between two vertically adjacent pixels is fixed at 2,048 multiplied by the pixel format in bytes. This means that when reading or writing image data through virtual addresses, there must be an offset of: (2048 – IMAGEWIDTH) × PS bytes at the end of every line.
- Base address alignment:  
For optimization, the base address is aligned on the page size. For instance, a 1K-byte page size organized as a 32 × 32-byte page is aligned on 0x400 (to be adjusted on the base address).
- To improve performance on 90° rotation consider two things:
  - Because a read access can appear more critical than a write access, a posted write may be appropriate.
  - When performing burst accesses with 90° or 270° rotation views, the burst is split on the memory side, adding latency.  
For a burst access with 90° rotation, split the data of the burst on the write side (not the read side):
    - Write in 270° and read in 0°.

## 1.2.6.2 SMS Mode of Operation

### 1.2.6.2.1 The SDRAM Memory Scheduler and Arbitration Policy

The SDRAM memory scheduler improves access to external memory by:

- Optimizing SDRAM bandwidth
- Prioritizing requests to external memory

This mechanism relies on a complex arbitration policy that employs specific terminology:

- Group: a FIFO queue of requests from initiators
- Class: A collection of groups
- Transaction: A full burst request
- Arbitration grant: Authorization of a service requested by an initiator

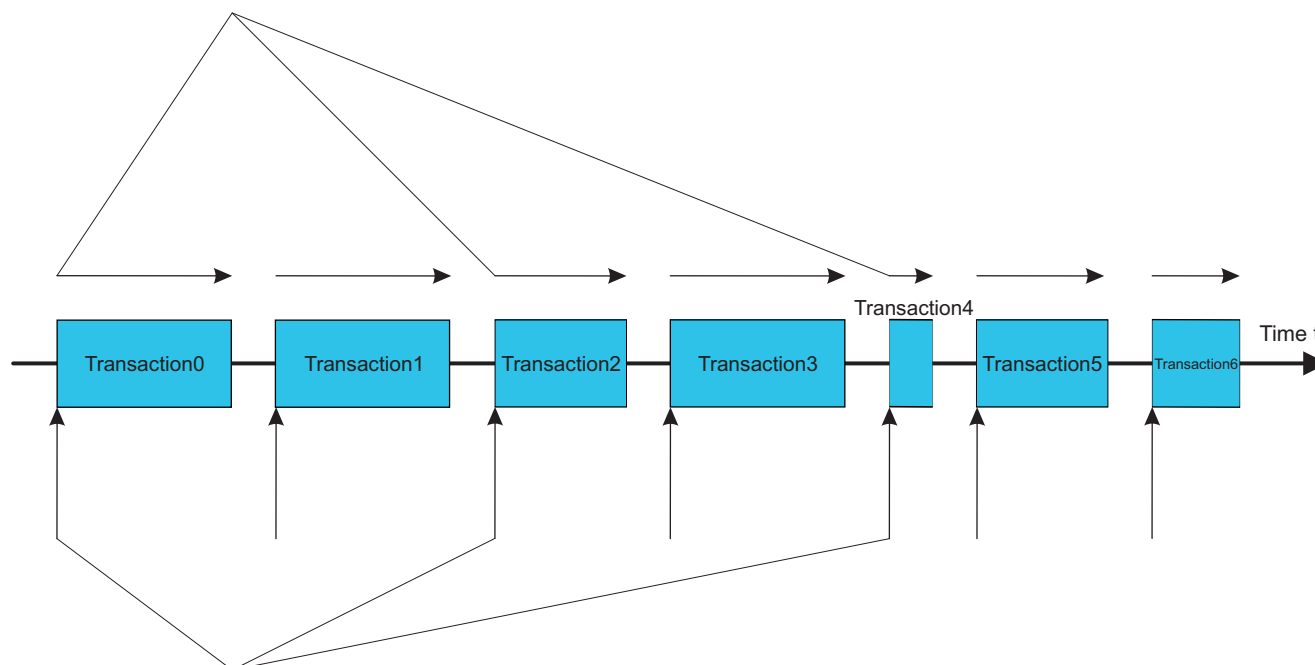

The arbitration policy operates on two interdependent mechanisms:

- The arbitration decision, which establishes priority for processing requests. The question: Which request is processed next? occurs on a transaction boundary.
- Arbitration granularity, which determines the length of an arbitration grant. The question: How long to keep the grant? defines the boundary of the arbitration decision point in time.

Figure 1-66, shows the link between these two concepts. On a transaction boundary, the questions: What request is serviced next, and for how long? merge the two mechanisms. The mechanisms for specifying the granularity of requests also influence the boundary of a transaction.

**Figure 1-66. Arbitration Granularity Versus Arbitration Decision**

Duration of a transaction:  
How long to track the transaction?  
(it depends on the granularity settings)

Arbitration decision on a transaction boundary:  
Which group has the priority?

sdrc-024

### 1.2.6.2.2 The Arbitration Decision

The SMS module controls arbitration. Requests from initiators for access to the external SDRAM are collected into several independent FIFO queues, and each queue is assigned to a class. Priority is then assigned to groups and classes; this defines the next request to be serviced.

#### 1.2.6.2.2.1 Burst-Complete Mechanism

The burst-complete mechanism applies granularity to the arbitration scheme. Access cannot be granted to a group within a class until a complete burst has been stored in the FIFO.

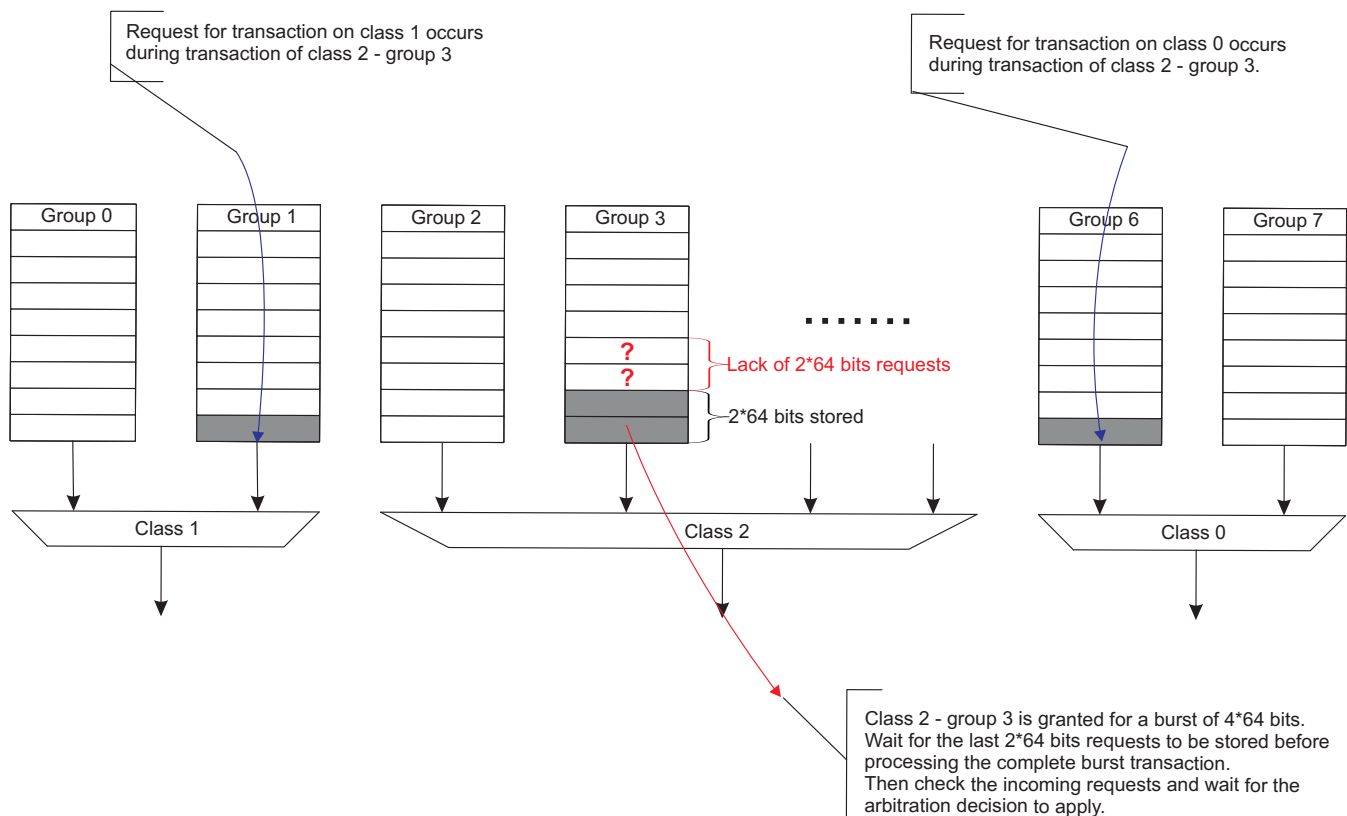

Example:

There is no ongoing transaction on Class 0. The initiator requests a  $4 \times 64$ -bit burst on Group 3 of Class 2 (SMS\_CLASS\_ARBITER2[27] BURST-COMPLETE = 0x1). Only  $2 \times 64$ -bit requests are stored in the FIFO.

The mode of operation is:

- Wait for the last  $2 \times 64$ -bit request to be stored in the FIFO.
- Arbitration is requested once all requests of a burst have been received.
- After the  $4 \times 64$ -bit burst is complete, the transaction occurs.
- The arbitration choice mechanism resumes:
  - Were there any incoming requests during the last transaction?
  - What is the next request to be serviced/granted?

**Figure 1-67. BURST-COMPLETE on Class 2-Group 3**

### 1.2.6.2.2.2 Priority Between Groups

The SMS.SMS\_CLASS\_ARBITERi[7:6] HIGHPRIOVECTOR field defines the priority between groups in a class.

### 1.2.6.2.2.3 Priority Between Classes

Class 0 always has the highest priority. Then you program a weight within the arbitration of Class 1 and Class 2:

- The SMS.SMS\_INTERCLASS\_ARBITER[23:16] CLASS1PRIO field specifies the number (M) of transactions dedicated to Class 1.
- The SMS.SMS\_INTERCLASS\_ARBITER[7:0] CLASS2PRIO field specifies the number (N) of transactions dedicated to Class 2.

M and N parameters are used to set a PWM arbitration. For instance, two schemes appear: at time t, Class 1 is serviced for M cycles, directly followed by service to Class 2 for N cycles. On the opposite, If Class 2 is serviced first for N cycles, then Class 1 is granted for M cycles. Arbitration is given more importance; Class 1/2 is favored over Class 2/1. As shown in [Figure 1-68](#), two arbitration schemes can appear:

- Class 0 is serviced first, followed by Class 1, then Class 2 (C0 - C1 - C2).
- Class 0 is serviced first, followed by Class 2, then Class 1 (C0 - C2 - C1).

**Figure 1-68. Priority Between Classes**

SMS\_INTERCLASS\_ARBITER[7:0] CLASS1PRIO field:  
defines the number M of transactions dedicated to class 1.

SMS\_INTERCLASS\_ARBITER[23:16] CLASS2PRIO field:  
defines the number N of transactions dedicated to class 2.

sdrc-026

### 1.2.6.2.3 Arbitration Granularity

Arbitration is the mechanism that give more or less importance to incoming requests depending on the initiator origin. Granularity influences the boundary of a transaction because it imposes the following questions:

- How many requests to service?
- How long to track the current transaction?
- When to make the next arbitration decision, or when does the next transaction boundary occur?

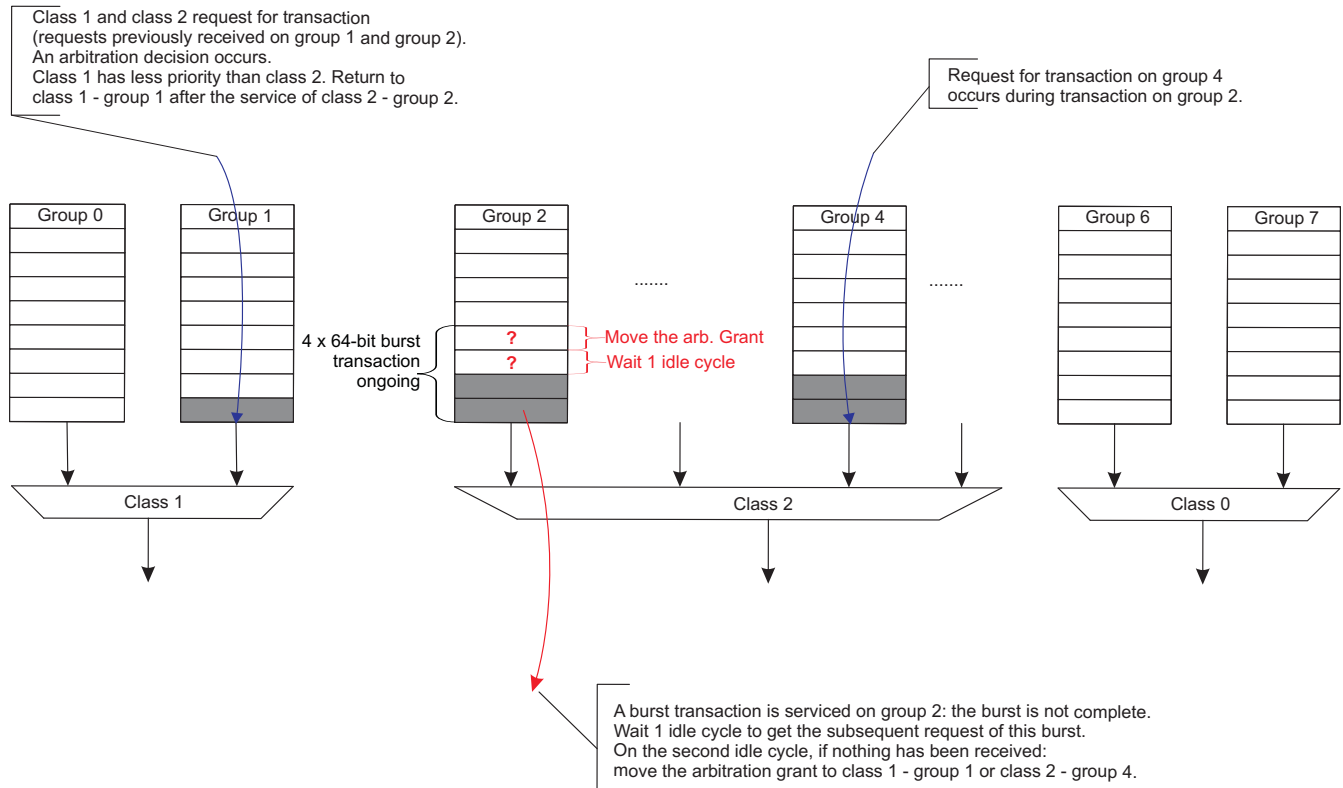

#### 1.2.6.2.3.1 Idle Cycle

The idle gives more granularity to the arbitration; it lets the arbiter wait one idle cycle before moving the arbitration grant to another thread.

Within a burst (see [Figure 1-69](#) for an example):

1. A thread requests a burst transaction. According to the thread ID, the last request was serviced on Class 2 – Group 2.
2. The thread cannot provide the subsequent request of the burst. The module waits for one idle cycle without moving the arbitration grant, to receive the subsequent request (from the same thread).
3. On the second idle cycle, if the subsequent request has not been received, the arbitration grant is moved so that a request from another thread is serviced.

**Figure 1-69. Idle Cycle Mechanism within a Burst**

sdrc-027

Two bursts must be serviced at the burst boundary. One idle cycle after servicing these two bursts, the arbitration grant is moved.

#### 1.2.6.2.3.2 Extended-Grant Mechanism

The extended-grant mechanism gives additional granularity to the arbitration. An extended grant defines the number of consecutive transactions (from 1 to 3) a group is granted.

Example:

Requests were already available on Class 1-Group 0 and Class 2-Group 3.

An arbitration decision occurs: grant access to Class 1-Group 0.

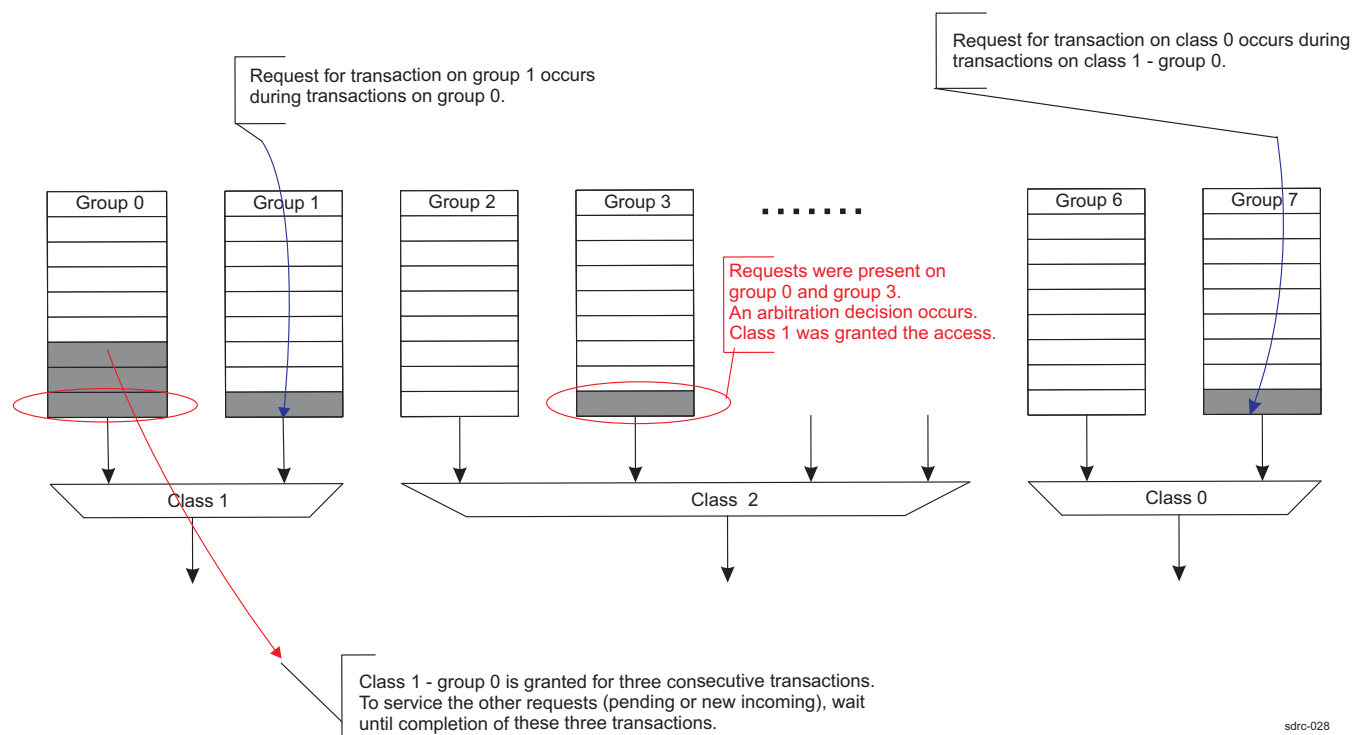

A request is now being serviced on Class 1-Group 0 with SMS\_CLASS\_ARBITER1[9:8]

EXTENDEDGRANT = 0x3 (three consecutive transactions are granted to Group 0). The mode of operation is:

- Process the request for three cycles.
- If another request comes from another class (even Class 0) during the processing, it is ignored; the arbiter does not treat incoming requests.
- After three consecutive transactions, return to the arbitration decision:
  - Were there any incoming requests during the last transaction?
  - What is the next request to be serviced?

Figure 1-70 shows this mechanism on Class 1 - Group 0:

**Figure 1-70. Example of EXTENDEDGRANT Mechanism**

### 1.2.6.2.3.3 Number of Service Mechanism.

The SMS\_CLASS\_ROTATIONm[4:0] NOFSERVICES field defines the number of consecutive transactions (from 1 to 31) the VRFB is granted. For more information on LRU policy and Number of Service, refer to [Section 1.2.4.1.3](#).

### 1.2.6.2.4 How these Mechanisms Interact

As described in the previous sections, the arbitration within the SMS module is based on several mechanisms giving even more importance to the arbitration. When we need to grant the access on a transaction boundary, we recall that the question we have to answer is: what will be the next request to be serviced and for how long?

Thus, the two important concepts regarding the SMS mode of operation are:

- The arbitration decision: we choose the next request to be serviced and so we grant it the access to the external memory.
- The arbitration granularity: depending on the mechanism used, we define the boundary of the transaction: how long do we keep the grant?

[Figure 1-71](#) describes the decision happening between classes.

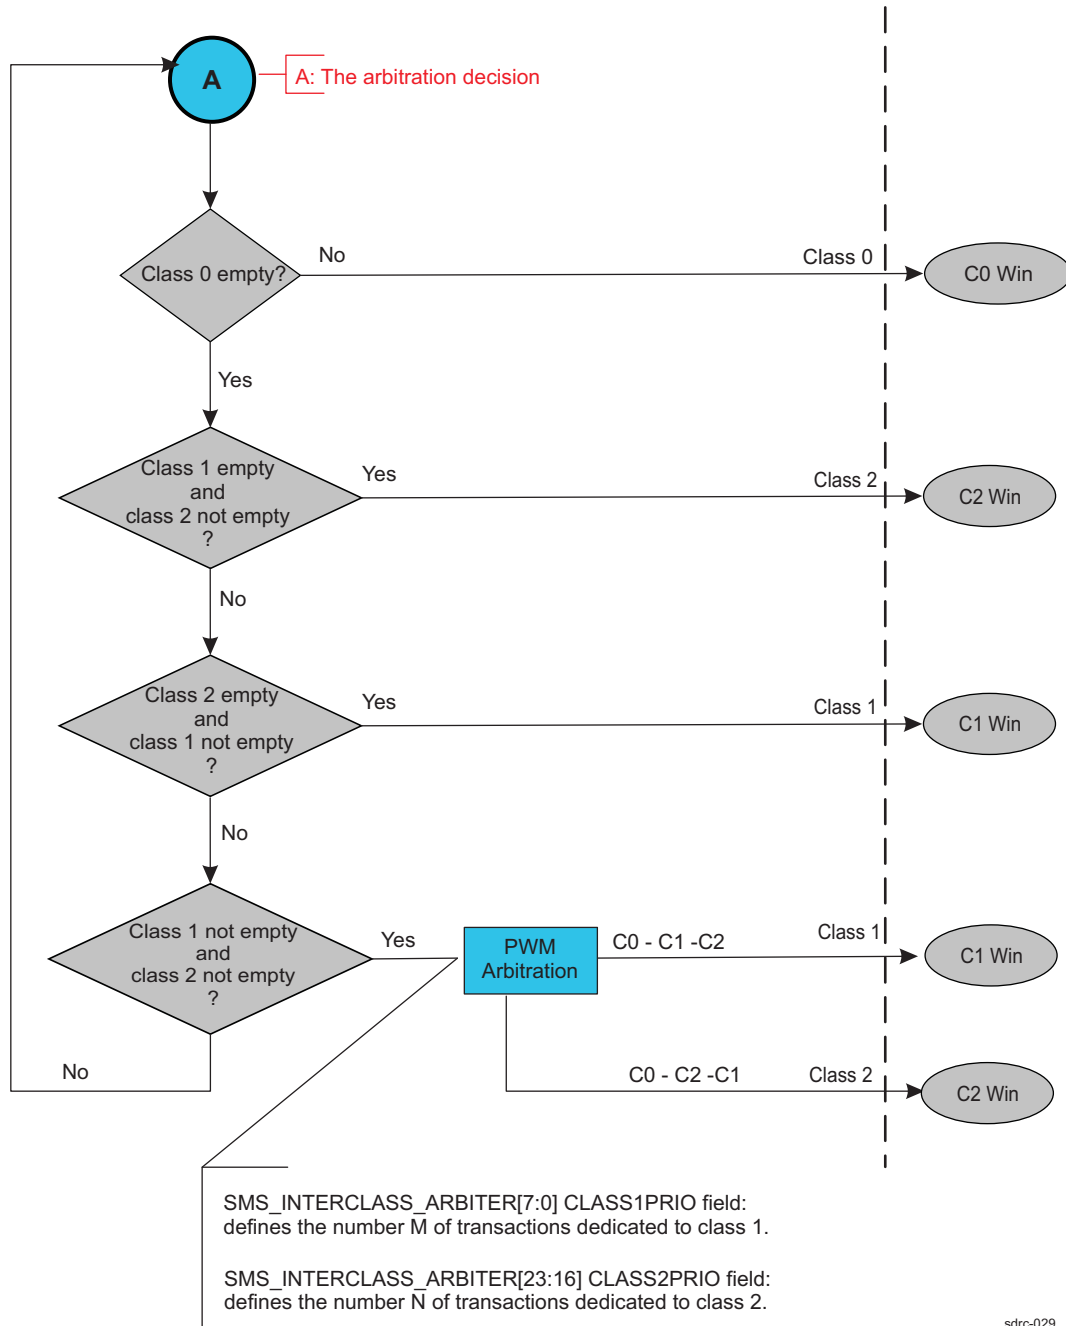

[Figure 1-72](#) explains the priority between groups within Class 1.

So far, the arbitration decision has taken place at class boundaries and within a class containing 2 groups.

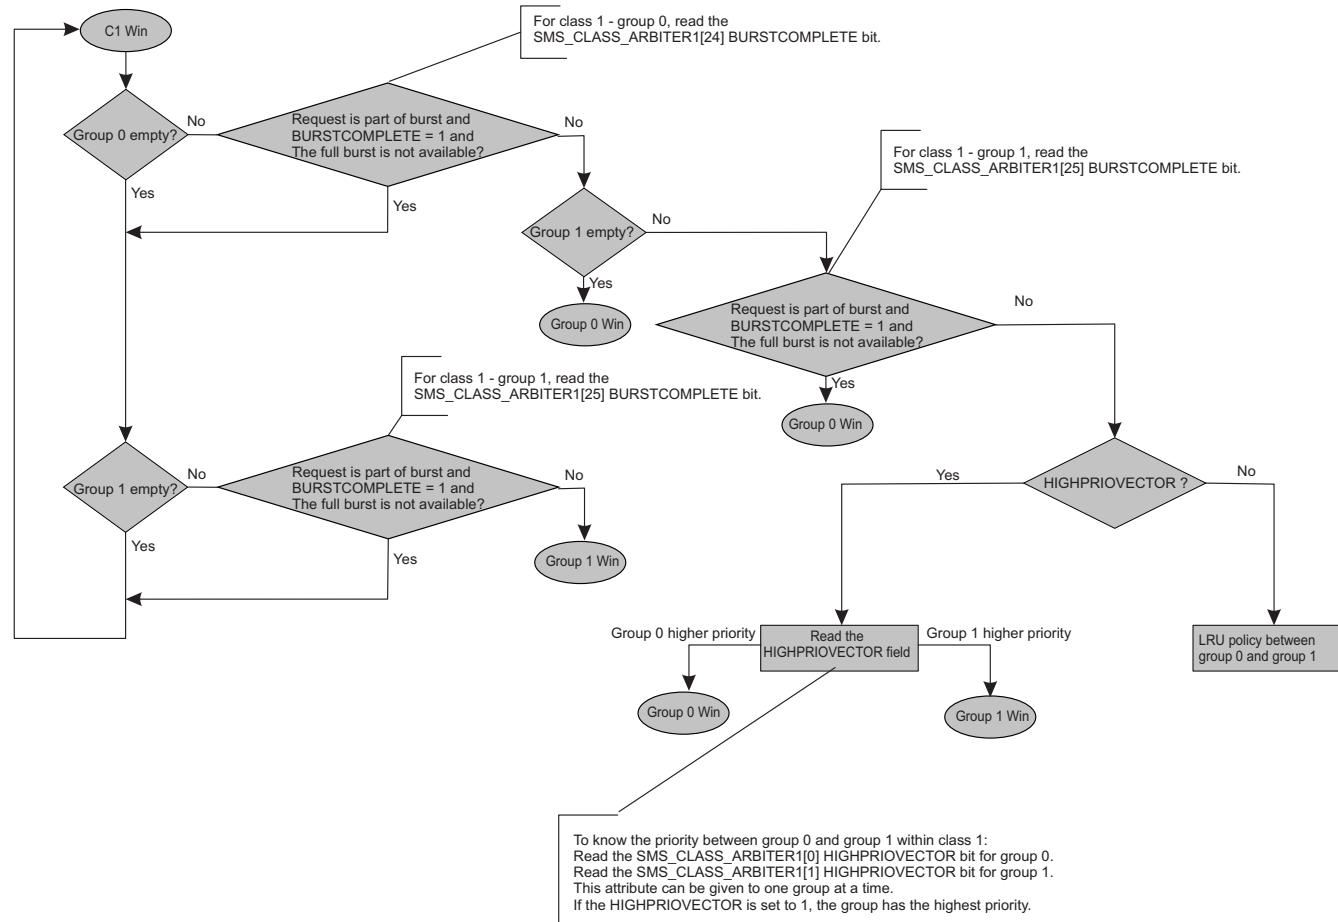

[Figure 1-73](#) recalls the generic way to service and so prioritize the requests within a class.

Finally, [Figure 1-74](#) recalls mechanisms used to define the boundary of the transaction being serviced (how long do we keep the grant?).

### 1.2.6.3 Typical SDRC Connection to an External SDRAM Device

The SDRAM controller (SDRC) transfers data to and from standard SDRAM based on user request. It interfaces between an external SDRAM memory subsystem and the SDRAM Memory Scheduler that optimizes memory access for each application.

This section shows a typical connection between the SDRC module and an external SDRAM. The use case explains important parameters and their required configurations.

#### 1.2.6.3.1 External Memory Attached to the SDRC Module

The SDRC module supports the following external memory types:

- Low-power DDR SDRAM device

This section describes how to calculate the SDRC timing parameters and provides a typical setup of those parameters according to the access performed.

A 512 Mb mobile DDR SDRAM memory with the following characteristics has been chosen:

- Type: Mobile DDR SDRAM
- Size: 512 Mbits ( $8M \times 16 \times 4$  banks)
- Data bus: 16-bit width
- Speed: 133-MHz clock frequency, 7.5-ns clock period

#### 1.2.6.3.2 DDR-SDRAM Memory General Facts

This section details the interconnection of the Mobile DDR SDRAM with the SDRC interface; it then gives a basic SDRAM workflow and introduces the difference between the autorefresh and self-refresh concepts.

##### 1.2.6.3.2.1 Mobile DDR Interconnection with SDRC

Figure 1-75 shows a simplified interconnection diagram of the mobile DDR SDRAM with the SDRC interface.

Figure 1-75. Mobile DDR SDRAM to SDRC Interface

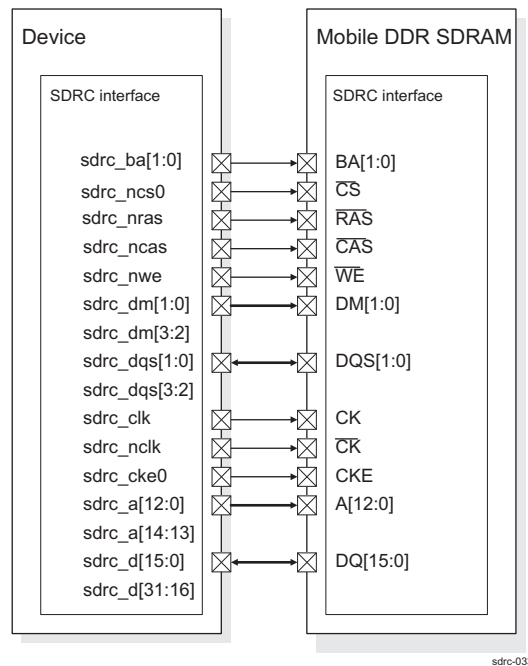

Table 1-74 recalls SDRC module's I/Os from a SDRC point of view.

**Table 1-74. SDRC Signals Description**

Signal Name	I/O <sup>(1)</sup>	Description
sdrc_clk, sdrc_nclk	O	Address and control input signal sample clock
sdrc_cke0	O	Clock-enable signal
sdrc_ncas, sdrc_nras, sdrc_nwe	O	Column address strobe, row address strobe, and write enable. Defines the command being entered
sdrc_ba0, sdrc_ba1	O	Bank address outputs
sdrc_dm[3:0]	O	Data mask. sdrc_dm[0] corresponds to the data on sdrc_d[7:0]; sdrc_dm[1] corresponds to the data on sdrc_d[15:8]. sdrc_dm[3:2] unconnected.
sdrc_ncs0	O	Chip-select for external SDRAM selection (only one enabled here)
sdrc_a[12:0]	O	Address bus sdrc_a[14:13] unconnected.
sdrc_d[15:0]	I/O	Data bus sdrc_d[31:16] unconnected.
sdrc_dqs0, sdrc_dqs1	I/O	DDR data strobe. Output with read data, input with write data sdrc_dqs[3:2] unconnected.

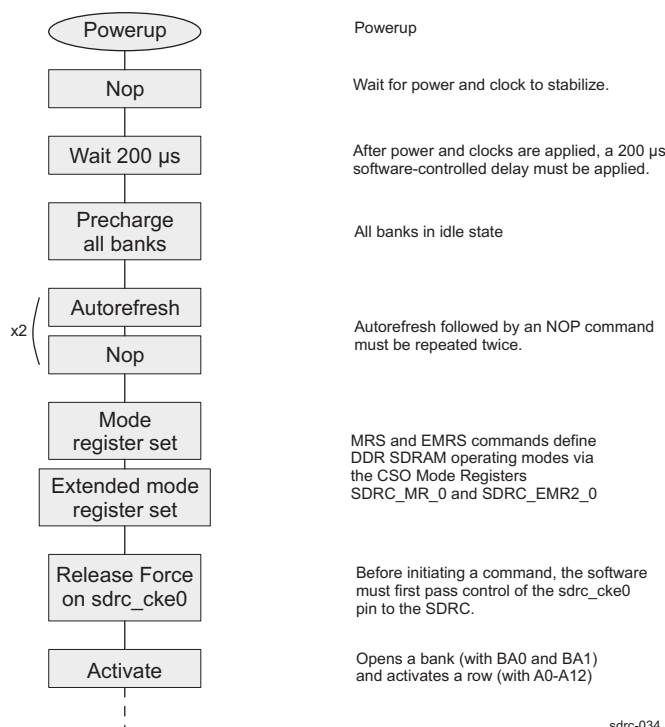

<sup>(1)</sup> I = Input; O = Output

### 1.2.6.3.2.2 SDRAM Operating Flow

This section illustrates the basic DDR-SDRAM workflow. For more information on SDRAM operation, refer to the *Low Power Double Data Rate (LPDDR) SDRAM* specification (JEDEC committee JC42.3) or to the Mobile DDR SDRAM documentation.

Figure 1-76 shows a simplified operating diagram of the power up sequence required to correctly power up an SDRAM.

Figure 1-77 shows a simplified diagram of the normal operating sequence.

**Figure 1-76. SDRAM Powerup Sequence**

**Figure 1-77. Normal Operating Sequence**

#### 1.2.6.3.2.3 Autorefresh vs Self-Refresh

What are the differences between an autorefresh and a self-refresh?

DDR SDRAM devices require a refresh of all rows in 64 ms intervals as specified in the JEDEC LPDDR SDRAM standard. The autorefresh period may depend on the technology. Each refresh is generated either by an autorefresh command from the SDRC in normal mode, or by an internal counter in the SDRAM in self-refresh mode.

The autorefresh command must be generated each time a refresh is required. The average refresh interval period (tREFI), also called autorefresh duty cycle, is given by the division of 64 ms into the number of rows (8192 for the selected mobile DDR SDRAM). An internal refresh controller in the SDRAM takes care of the refreshing process and control, and the autorefresh command must be issued regularly by the SDRAM controller.

The self-refresh command is used when the system is powered down and enables data retention even if the clock is stopped.

For more information on refresh modes, see [Section 1.2.4.4.7, Refresh Management](#).

### 1.2.6.3.3 SDRC Typical Setup

When a given external memory device has been selected, the SDRC must be configured according to the memory parameters.

#### 1.2.6.3.3.1 Memory Type General Configuration

[Table 1-75](#) summarizes the mobile DDR SDRAM address configuration.

**Table 1-75. Mobile DDR SDRAM Address Configuration**

Item	Description
RAM size	512 Mbits
Number of banks	4
Bank address pins	BA0, BA1
Row addresses	A0-A12
Column addresses	A0-A9
tREFI (μs)	7.8

The following parameters must be configured in register SDRC.SDRC\_MCFG\_p, where p = 0 (configuration register for the SDRAM connected to the sdrc\_ncs0) as follow:

- SDRC\_MCFG\_p[19] ADDRMUXLEGACY = 0x1 selects the flexible address mux scheme.
- SDRC\_MCFG\_p[1:0] RAMTYPE = 0x1 selects DDR-SDRAM.
- SDRC\_MCFG\_p[2] DDRTYPE = 0x0 is the default setting that sets the DDR memory type as mobile DDR.
- SDRC\_MCFG\_p[17:8] RAMSIZE = 0x020 is the RAM address space size expressed in 2-Mbyte chunks. In this example, the DDR SDRAM size is 512 Mbits or 64 Mbytes. These are 32 2-Mbyte chunks, that is, 20 2-Mbyte chunks expressed in hexadecimal format.
- SDRC\_MCFG\_p[4] B32NOT16 = 0x0. The external SDRAM bus width is 16-bit.
- SDRC\_MCFG\_p[26:24] RASWIDTH = 0x2 because RAS width is 13 bits.
- SDRC\_MCFG\_p[22:20] CASWIDTH = 0x5 because CAS width is 10 bits.
- SDRC\_MCFG\_p[3] DEEPPD = 0x1. The memory device supports deep-power-down mode.
- Other bit fields as LOCKSTATUS and BANKALLOCATION may be set up as required.

#### 1.2.6.3.3.2 Mode Register Configuration

The SDRAM mode of operation is defined through the mode register as follow (p = 0 for CS0):

- SDRC\_MR\_p[6:4] CASL = 0x3. The CAS latency, or read period, is 3 clock cycles long.
- SDRC\_MR\_p[2:0] BL = 0x2. The memory burst length must be set at 4 for DDR SDRAM.
- SDRC\_MR\_p[3] SIL = 0x0. The serial mode is always used.
- SDRC\_MR\_p[9] WBST = 0x0. Write burst equals read burst.

To configure the DLL/CDL module as second clock write path, set up the SDRC\_DLLA\_CTRL register as follows:

- SDRC\_DLLA\_CTRL[7] WRITEDDRCLKX2DIS = 0x1 so that the DLL/CDL write path can be used as mobile DDR write path.
- SDRC\_DLLA\_CTRL[3] ENADLL = 0x1 enables the DLL.
- SDRC\_DLLA\_CTRL[2] LOCKDLL must be set to 0 for high-speed operations.
- SDRC\_DLLA\_CTRL[1] DLLPHASE. 0x0 for read accesses or 0x1 for write accesses. This respectively corresponds to a CDL delay of a quarter of a clock period or a fifth of a clock period.

The recommended configuration is to use the data path using double frequency logic rather than the DLL/CDL write path. This is obtained by setting WRITEDDRCLKX2DIS to 0x0.

### 1.2.6.3.3.3 SDRAM Programmable AC Timing Parameters Configuration

Some parameters are hard-coded in the SDRC. Apart from those parameters, users can program a list of programmable AC timings via the SDRC\_ACTIM\_CTRLA\_p and SDRC\_ACTIM\_CTRLB\_p registers, where  $p = 0$  or  $1$ , depending on the SDRAM chip (in the section  $p = 0$ , since only one chip is connected to the SDRC interface). The setup values are expressed in clock cycles.

[Table 1-76](#) summarizes the most important AC timing parameters to be configured.  $F = 133$  MHz and  $tCK = 7.5$  ns for the clock signal.

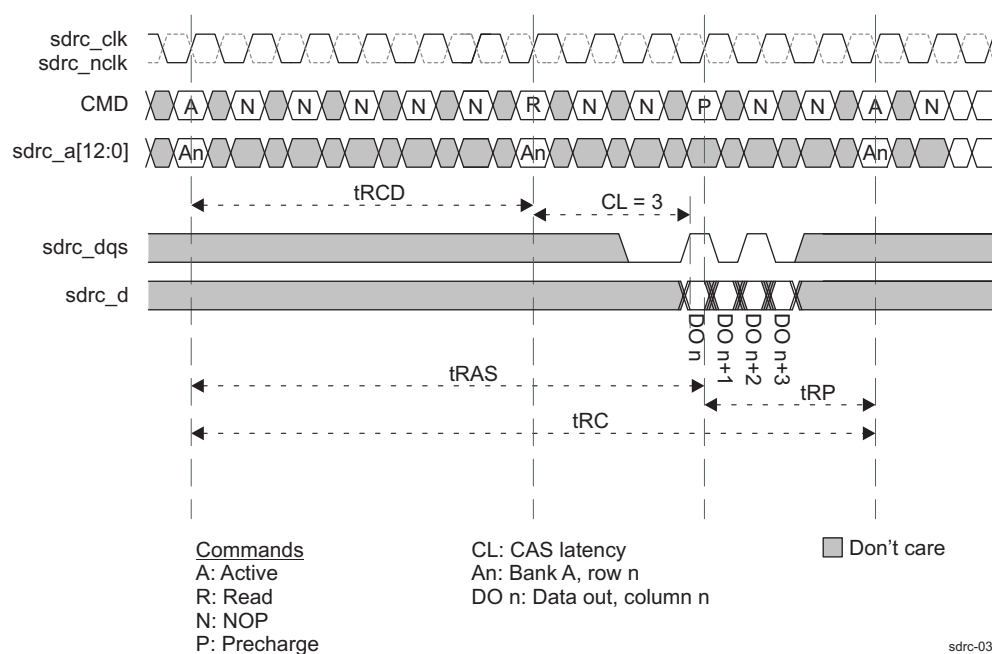

**Table 1-76. Mobile DDR SDRAM AC Timings Parameters**

AC Timing Parameter	Description	Duration (ns)
tRC	Row cycle time	67.5 (or 9 tCK)
tRAS	Row active time	45 (or 6 tCK)
tRP	Row precharge time	22.5 (or 3 tCK)
tRCD	nRAS to nCAS delay time	22.5 (or 3 tCK)
tRFC	Autorefresh cycle time	80 (min)
tRRD	Row active to row active delay time	15 (or 2 tCK)
tDPL	Data-in to precharge command time or tWR (write recovery time)	15 (or 2 tCK)
tWTR	Write-to-read time (also called tCDLR). Last data in to read command	1 tCK
tCKE	CKE minimum pulse width time (high and low pulse width)	2 tCK
tDAL	Last data in to active delay time	2 tCK + tRP
tXSR	Exit self-refresh to active command time	120
tXP	Exit power-down to active command time	25

Before calculating the timing parameters on the SDRC side, let's define some terms used to describe the timing between the controller and the memory device:

- nRAS to nCAS delay time is the row-activating phase, or minimum time between an ACTIVE and a READ or WRITE command.
- CAS latency is the time between a READ or a WRITE command and the data driven on DQ lines. With  $CL = 3$ , the first data element is valid at  $(2 \times tCK + tAC)$  after the clock at which the READ command is registered. With  $CL = 2$ , the first data element is valid at  $(tCK + tAC)$  after the clock at which the READ command is registered.  $tAC$  is the DQ output window relative to the clock, and is the long term component of DQ skew.
- Row active time is the minimum bank activate to PRECHARGE time. A PRECHARGE cannot start until tRAS has elapsed.
- Row precharge time: Following the PRECHARGE command, a subsequent command to the same bank cannot be issued until tRP is met. After tRP, an ACTIVE command to the same bank can be initiated.
- Row cycle time is the minimum time between the activation of a first row and the activation of another row in the same bank. It is also called ACTIVE to ACTIVE command period.
- Last data in to active delay time is the minimum time between the last data in and the next ACTIVE command.
- Autorefresh cycle time: Refreshing starts with an AUTO REFRESH command and ends when tRFC is met.

[Figure 1-78](#) shows a simplified timing diagram of a burst read of SDRAM.

**Figure 1-78. SDRAM Burst-Read Timing Diagram**

The SDRC\_ACTIM\_CTRLA\_p register (p = 0) must be programmed with the AC timing parameters listed in [Table 1-77](#). Values are expressed in number of tCK periods.

**Table 1-77. Calculation of the SDRC.SDRC\_ACTIM\_CTRLA\_p Timing Parameters**

DDR-SDRAM Parameter Name	Number of Clock Cycles (F = 133 MHz, tCK = 7.5 ns)	SDRC_ACTIM_CTRLA_p Bit Field Value
tRC	9	TRC = 0x09
tRAS	6	TRAS = 0x6
tRP	3	TRP = 0x3
tRCD	3	TRCD = 0x3
tRFC	80 / 7.5 (minimum)	TRFC = 0x0B
tRRD	2	TRRD = 0x2
tDPL	2	TDPL = 0x2
tDAL	2x1 + 4 (in clock cycles)	TDAL = 0x6

The SDRC\_ACTIM\_CTRLB\_p (p = 0) register must be programmed with the AC Timing Parameters listed in [Table 1-78](#). Values are expressed in number of tCK.

**Table 1-78. Calculation of the SDRC.SDRC\_ACTIM\_CTRLB\_p (p = 0) Timing Parameters**

DDR-SDRAM Parameter Name	Number of Clock Cycles (F = 133 MHz, tCK = 7.5 ns)	SDRC_ACTIM_CTRLB_p Bit Field Value (p=0)
tCDLR	1	TWTR [17:16] = 0x1
tCKE	2	TCKE [14:12] = 0x2
tXP	25 ns <sup>(1)</sup>	TXP [10:8] = 0x4
tXSR	120 / 7.5	TXSR [7:0] = 0x10

<sup>(1)</sup> JEDEC LPDDR SDRAM standard states 25 ns with a minimum of 1 clock period.

#### 1.2.6.3.3.4 Autorefresh Management Configuration

In normal operation mode, the autorefresh is managed by the SDRAM refresh configuration register `SDRC_RFR_CTRL_p` (where  $p = 0$ ). The autorefresh counter is uploaded with the result of  $(t_{REFI} / t_{CK}) - 50$ .

50 (cycles) is a margin in case a command is already in progress on the SDRAM interface, thus requiring delay before initiating the autorefresh command. See [Section 1.2.5.3.6, Autorefresh Management](#), for more details.

[Table 1-79](#) details the required configuration.

**Table 1-79. Calculation of the SDRC.SDRC\_RFR\_CTRL\_p ( $p = 0$ ) Timing Parameter**

DDR-SDRAM Parameter Name	Contents Formula	SDRC_RFR_CTRL_p Bit Field Value ( $p=0$ )
Autorefresh counter value	$(7.8 \mu s / 7.5 ns) - 50$	ARCV [23:8] = 0x03DE
Autorefresh enable	Load Autorefresh counter with 8 for maximum Autorefresh burst length	ARE [1:0] = 0x3

#### 1.2.6.4 Camcorder Use Case: How to Configure the VRFB

##### 1.2.6.4.1 Overview

This section discusses the configuration of the VRFB for rotating the video from the camera subsystem. The VRFB receives a video from the camera subsystem as a sequence of images. These images are then saved into SDRAM through the SDRC. [Figure 1-79](#) is an overview of the VRFB in the camcorder use case.

**Figure 1-79. SDRC Camcorder Use Case Overview**

After the VRFB configuration, the rotation process is transparent to the MPU operations. Four buffers are required in SDRAM to ensure stabilization, a smooth encoding process, and a tearing-free preview on the LCD display. Each of the four buffers uses a concurrent context. For each context, the following parameters must be configured:

- Page and pixel size
- Picture parameter (image height and width)
- Buffer physical base address

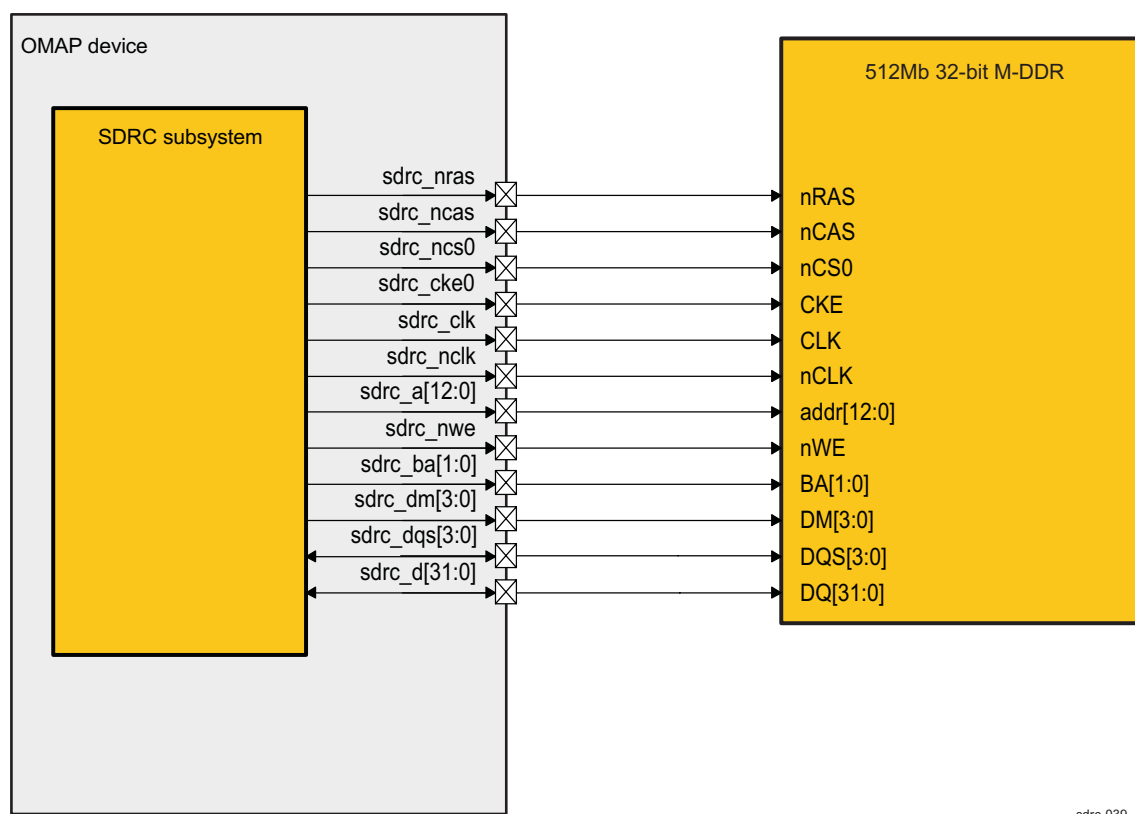

### 1.2.6.4.2 Environment

In this use case, the SDRC controller is connected to an external 512Mb 32-bit Mobile DDR SDRAM 166-MHz device (16M × 32).

The SDRC\_CLK clock source fed to the SDRAM is the PRCM CORE\_L3\_ICLK output.

The SDRAM device is connected to the SDRC subsystem (see [Figure 1-80](#)). For more information on the SDRC environment, see [Section 1.2.2, SDRC Subsystem Environment](#).

**Figure 1-80. SDRC Camcorder Use Case Environment**

sdrc-039

### 1.2.6.4.3 Data Path

In this use case, the VRFB manages the rotation of the video stream, which is a sequence of images in YUV 4:2:2 format received from the camera subsystem.

- Write actual image received from the camera subsystem into SDRAM through the VRFB in the first view (0°).
- Display the image in SDRAM on the external display through the display subsystem in any of the four available VRFB views (0°, 90°, 180°, or 270°).

See [Figure 1-65](#) for the VRFB data path of this use case.

The row increment in the SDRAM is programmed in the display subsystem registers and depends on the VRFB rotation angle.

#### 1.2.6.4.4 Programming Flow

A main function automatically configures the VRFB contexts. This function is called four times to configure each of the four contexts. For each context, a set of parameters is given to the function:

- The actual image width and height (from the camera subsystem)
- The physical address (of the given context)
- The rotation of the context

The main function initializes the VRFB in three steps:

1. Virtual frame buffer configuration. This is done with a page size calculation function, as described in [Section 1.2.6.4.4.1](#).
2. Image size configuration. This is done with a picture size calculation function, as described in [Section 1.2.6.4.4.2](#).
3. Physical base address configuration, as described in [Section 1.2.6.4.4.3](#).

##### 1.2.6.4.4.1 Page Size Calculation Function

The page size is configured through three parameters: page width (PW), page height (PH), and pixel size (PS). The three page size parameters are configured into the SMS\_ROT\_CONTROLn registers, where n is the context number (n = 0 to 3):

- Page width: SMS\_ROT\_CONTROLn[6:4] PW. The PW parameter defines the page width according to the value of  $2^{PW}$  bytes.
- Page height: SMS\_ROT\_CONTROLn[10:8] PH. The PH parameter defines the page height according to the value of  $2^{PH}$  lines.
- Pixel format: SMS\_ROT\_CONTROLn[1:0] PS. The PS parameter defines the pixel size according to the value of  $2^{PS}$  bytes. In this use case, the pixel size is a constant linked to the YUV 4:2:2 format. For more details about YUV 4:2:2 format, see [Section 1.2.6.1.2, Setting a VRFB Context](#).

The recommendation is to have a squared page arrangement. The page can be defined as a 32-byte × 32-byte array (1024-byte page) or 16-byte × 16-byte array (256-byte page). This arrangement is pixel-based, which means the pixel size must be part of the calculation. Other settings are possible, but from a performance point of view it is recommended to have the page size consistent with the SDRAM page (that is, 2K bytes for the Mobile DDR SDRAM).

In this use case, however, the page size calculation function defines the page width and the page height. The pixel size is not part of the calculation. Hence, instead of having a 64 × 32 page (because a pixel takes 2 bytes) the function calculates a 32 × 32 page. This gives a page size of 1K-byte, and memory area usage is optimized.

First, the function checks whether the width of the image received from the camera is a multiple of 32 bytes. If the width is not a multiple of 32 bytes, the function checks whether the image is a multiple of 16 bytes. If the image from the camera is neither a multiple of 32 bytes nor 16 bytes, the function sets the page width to 32 bytes as the default. In this use case, the image received from the camera has a width of 736 pixels.

1. Check that 736 is a multiple of 32:  $736 / 32 = 23$ . It is. As a consequence, the page width is 32 (bytes).
2. Configure a page width of 32 with the  $2^{PW}$  bytes formula: SMS\_ROT\_CONTROLn[6:4] PW = 0x5.  
Then, the function checks whether the height of the image received from the camera is a multiple of 32 (rows). If the height is not a multiple of 32 (rows), the function checks whether the image is a multiple of 16 rows. If the image from the camera is neither a multiple of 32 rows nor 16 rows, the function sets the page height to 32 rows as the default. In this use case, the image received from the camera has a height of 560 lines.
3. Check that 560 is a multiple of 32:  $560 / 32 = 17.5$ . It is not.
4. Check that 560 is a multiple of 16:  $560 / 16 = 35$ . It is. As a consequence, the page height is 16 (lines).
5. Configure a page height of 16 with the  $2^{PH}$  lines formula: SMS\_ROT\_CONTROLn[10:8] PH= 0x4.  
The pixel format of this use case is YUV 4:2:2. Two pixels are stored on 4 bytes.
6. Configure a pixel size of four bytes with the  $2^{PS}$  bytes formula: SMS\_ROT\_CONTROLn[1:0] PS = 0x2.

### 1.2.6.4.4.2 Picture Size Calculation Function

The picture size is configured through two parameters: image width (IMAGEWIDTH) and image height (IMAGEHEIGHT). Two sizes must be distinguished:

- Actual image width and actual image height. This is the size of the image received by the camera subsystem.
- Programmed image width and programmed image height. This is the size of the image programmed in the VRFB.

Figure 1-81 shows the actual image width (IW) and image height (IH) versus the programmed image width ( $IW + \Delta IW$ ) and programmed image height ( $IH + \Delta IH$ ).

**Figure 1-81. VRFB Actual Image Size vs Programmed Image Size**

sdr-040

The programmed image size parameters are configured into the SMS\_ROT\_SIZE<sub>n</sub> registers, where n is the context number (n = 0 to 3):

- Image width: SMS\_ROT\_SIZE<sub>n</sub>[10:0] IMAGEWIDTH. This parameter is expressed in the number of pixels.
- Image height: SMS\_ROT\_SIZE<sub>n</sub>[26:16] IMAGEHEIGHT. This parameter is expressed in the number of pixels.

The picture size calculation function determines the required number of pages per line and per column using the page size calculated previously. That is a page width of 8 pixels (32 bytes and 4-byte pixel) and a page height of 16 pixels.

1. Determine the required number of pages per line with the formula:  

$$\left[ \left( \frac{\text{actual\_image\_width}}{2} \right) \frac{\text{pixels}}{\text{page\_width bytes}} \right] \times \text{pixel\_size bytes/pixel}$$
This gives a required number of pages per line of  $\left[ \left( \frac{736}{2} \right) / 32 \right] \times 4 = 46$ .  
If the number of pages per line is not an integer, it must be rounded up; for instance, if the result was 46.25 the number of pages required per line would be 47. Figure 1-81 shows this point.
2. Determine the required number of pages per column with the formula:  

$$\frac{\text{actual\_image\_height pixels}}{\text{page\_height lines}}$$
This gives a required number of pages per column of  $560 / 16 = 35$ .  
If the number of pages per column is not an integer, it must be rounded up.

Finally, calculate the programmed image size in pixels using the number of pages calculated above:

1. Calculate the programmed image width with the formula:  

$$\left( \text{rounded\_up\_number\_of\_pages\_per\_line} \times \text{page\_width bytes} \right) / \text{pixel\_size bytes/pixel}$$
This gives a programmed image width of  $(46 \times 32) / 4 = 368$ .

The function sets SMS\_ROT\_SIZE<sub>n</sub>[10:0] IMAGEWIDTH = 0x170.

2. Calculate the programmed image height with the formula:  
( rounded\_up\_number\_of\_pages\_per\_column × page\_height lines)  
This gives a programmed image height of (35 × 16) = 560.  
The function sets SMS\_ROT\_SIZE<sub>n</sub>[26:16] IMAGEHEIGHT = 0x230.

Because the actual image is a multiple of the page size (both width and height, as explained in [Section 1.2.6.4.4.1](#)), the actual image size and the programmed size are the same. In other words, ΔIW and ΔIH are null in this use case.

#### 1.2.6.4.4.3 Physical Base Address Configuration

The physical base address is the address of the picture in the external SDRAM. In this use case, the address space of CS0 is 512 Mbits, ranging from 0x8000 0000 to 0x83FF FFFF because the Mobile DDR SDRAM is a 512 Mbits memory device.

The physical address of the picture is a parameter entered by the user. It is directly written into the SMS\_ROT\_PHYSICAL\_BA<sub>n</sub>[30:0] PHYSICALBA bit field (where n = 0 to 11, for the 12 contexts).

#### 1.2.6.4.4.4 VRFB Use Case Summarizing Register Values

[Table 1-80](#) summarizes all the VRFB registers to be configured with the required values.

**Table 1-80. VRFB Use Case Summarizing Register Print**

Register Name	Context Number n	Physical Address	Value	Value Description
SMS_ROT_CONTROL <sub>n</sub>	0	0x6C00 0180	0x0000 0452	The page size is 8-pixel wide and 16-pixel high. This is a width of 32 bytes and a height of 16 lines. The pixel format is YUV 4:2:2 (2 pixels take 4 bytes).
	1	0x6C00 0190		
	2	0x6C00 01A0		
	3	0x6C00 01B0		
SMS_ROT_SIZE <sub>n</sub>	0	0x6C00 0184	0x0230 0170	Actual image size is 736 × 560. This gives 368 × 560 with the YUV 4:2:2 pixel format
	1	0x6C00 0194		
	2	0x6C00 01A4		
	3	0x6C00 01B4		
SMS_ROT_PHYSICAL_BA <sub>n</sub>	0	0x6C00 0188	0x8090 0000	Example of physical base address
	1	0x6C00 0198	0x8100 0000	
	2	0x6C00 01A8	0x8190 0000	
	3	0x6C00 01B8	0x8200 0000	

### 1.2.6.5 Understanding SDRAM Subsystem Address Spaces

#### 1.2.6.5.1 Physical vs Virtual Address Spaces

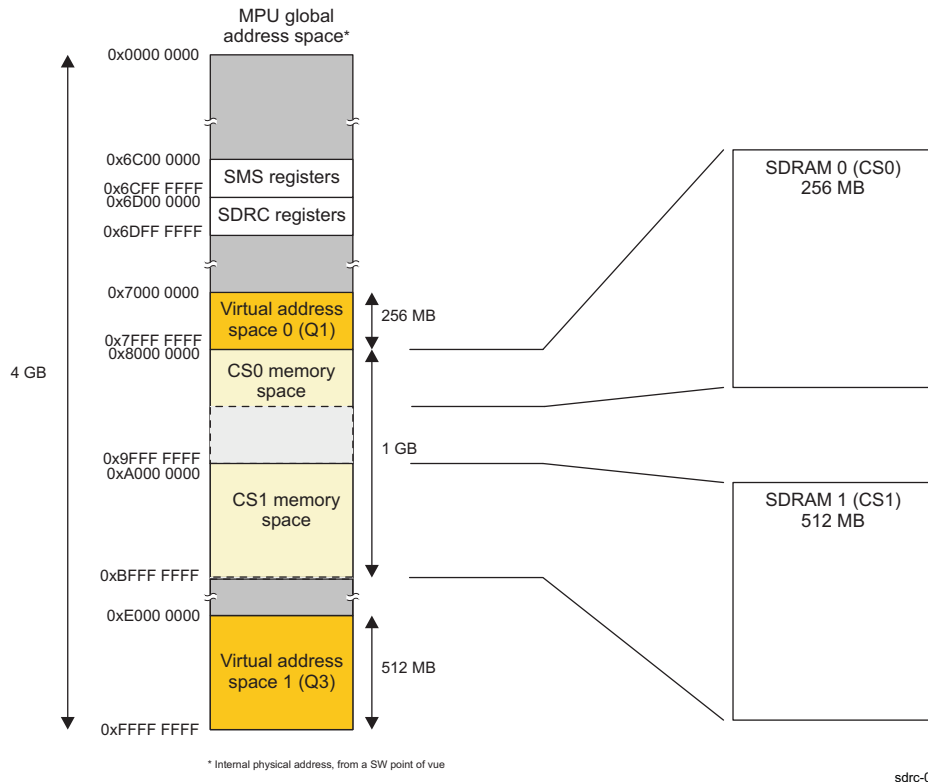

One thing that the SMS does is to translate virtual addresses into physical SDRAM addresses in case of rotation only, i.e. when accessing virtual address space 0 (quarter 1) and virtual address space 1 (quarter 3) as depicted in [Figure 1-82](#). The SMS then reinserts a request, or multiple requests depending on the SMS parameters, in the SMS request path to the SDRC controller (through the VRFB or not).

The SDRAM subsystem global memory space mapping reaches 1.768 GBytes:

- 1 GByte of CS memory space (CS0 and CS1 memory spaces): the SDRC controller automatically accesses the two external memory devices through direct accesses (addresses are simply translated).

- 768 MBytes of virtual address space (address space 0 and address space 1): the SDRC controller automatically accesses the two external memory devices through re-organized access (requests are modified accordingly to the context number and rotation angle before address translation). See section [Section 1.2.6.5.1.2](#) for more information on VRFB contexts and rotation angles.

**Figure 1-82. SDRC Address Space in MPU Global Address Space**

Configuration registers space is detailed in the following table:

**Table 1-81. SDRC and SMS Configuration Registers Space**

Module	Start Address	End Address	Total Space
SMS	0x6C00 0000	0x6CFF FFFF	16MB
SDRC	0x6D00 0000	0x6DFF FFFF	16MB

### 1.2.6.5.1.1 Physical Address Space

The physical address space of the SDRC is 1 GByte (maximum addressing capability).

The SDRC has a memory device capacity of 16 Mbits to 2 Gbits. 16 Mbits / 2 MBytes is the smallest granularity of supported memory device.

### 1.2.6.5.1.2 Virtual Address Space

The SDRC-SMS virtual memory space is a memory space used to access a subset of the SDRC memory space through the rotation engine (Virtual Rotation Frame Buffer). The virtual address space size is 768 MBytes split into two parts: the first 256-MByte part is in the second quarter (Q1) of the memory; the second 512-MByte part is in the fourth quarter (Q3) of the memory. See chapter 2, *Memory Mapping*, for more information on global memory mapping.

The VRFB is a rotation engine that:

- supports rotations of 0, 90, 180, and 270 degrees
- can handle up to 12 concurrent rotation contexts

The VRFB has therefore 48 different contexts in the virtual address space. [Table 1-82](#) gives the VRFB address-space memory locations at which the frame buffer object can be accessed. The table summarizes the virtual addresses of all 48 available image buffer from a global memory space (top level) point of view.

**Table 1-82. VRFB Contexts vs Rotation Angle**

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000

11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

The physical address of a page is calculated with the formula:

Physical address = Physical base address + Base address of page

where *Physical base address* is defined through the SMS\_ROT\_PHYSICAL\_BAn[30:0] PHYSICALBA field (buffer physical base address on which the rotation occurs), and *Base address of page* is the address obtain in function of the context number and rotation angle as given in [Table 1-82](#).

#### 1.2.6.5.2 CS Memory Spaces

Two SDRC chip-selects (sdrncs0 and sdrncs1) are available to access two external SDRAM memories.

##### 1.2.6.5.2.1 SDRAM Capacity Calculation

This section aims to explain how to calculate an SDRAM device capacity.

From the following SDRAM characteristics:

- 4 banks (BA0-BA1)
- Row addresses: A0-A12
- Column addresses: A0-A9
- 16-bit data bus to external memory

First calculate the number of addressable locations:

- Number of address lines: 13 (A0-A12)
- Number of banks address lines: 2 (BA0-BA1)
- Maximum number of rows = 13 (number of address lines used for row decoding)
- Maximum number of columns = 10 (number of address lines used for column decoding)

Total locations in a bank =  $(2^{13}) \times (2^{10})$

Then calculate the total locations in the device:

Total locations in the device = (Number of banks)  $\times$  (Total locations in a bank) =  $(2^2) \times (2^{13} \times 2^{10}) = 2^{25}$

Finally calculate the SDRAM device capacity:

Total device capacity = (Total locations in the device)  $\times$  (Device organization) =  $(2^{25}) \times (16) = 2^{29}$  bits

Hence, the device has a maximal capacity of 512 Mbits (or 64 MBytes).

In the same way, the SDRC maximal capacity can be calculated as follow:

- Number of address lines: 15 (A0-A14)
- Maximum number of rows = 15 (limited by the number of address lines, hence do not program SDRC\_MCFG\_p[26:24] RASWIDTH above 15)
- Maximum number of columns = 12 (limited by SDRC\_MCFG\_p[22:20] CASWIDTH)
- Data bus width to external device: 32-bit

SDRC total capacity =  $(2^{15} \times 2^{12}) \times 32 = 4$  Gbits (or 512 MBytes)

Hence, the SDRC has a maximum addressing capability of 8 Gbits / 1 GByte (as seen in [Section 1.2.6.5.1.1](#)) and can manage SDRAM devices with capacity of up to 4 Gbits / 512 MBytes (see caution below).

#### CAUTION

As the SDRC controller is aligned on the JEDEC LPDDR1 SDRAM standard, it is guaranteed that SDRAM with up to 1 Gbits capacity are supported. At the time of writing 2 Gbits and 4 Gbits Low Power DDR SDRAM are not yet in production and depending on their design (i.e. number of banks, page size, and other characteristics) these SDRAM might or might not be supported by the SDRC controller.

#### 1.2.6.5.2.2 CS Size

Each chip-select has its programmable size. The CS size is expressed in SDRC\_MCFG\_p[17:8] RAMSIZE (p = 0 or 1 for CS0 or CS1) as a number of 2-MBytes chunks.

For instance, when connecting a 256 Mbits SDRAM memory (see mux scheme MUX7 in table 1-2) to the SDRC controller, RAMSIZE must be set with the value 0x010 (32 MBytes = 2-MB  $\times$  16).

#### 1.2.6.5.2.3 CS Start and End Addresses

See figure [Figure 1-83](#), *CS0/CS1 Chip-Select Start Address Slots* for a graphical representation of CS starts addresses and CS size.

CS0 start address is fixed at :

- 0x0000 0000 from a SDRC point of view
- 0x8000 0000 from a global memory space point of view.

Hence, when connecting a 256 Mbits / 32 MBytes SDRAM memory (16M  $\times$  8 such as in MUX6, [Table 1-62](#)), CS0 end address is 0x0200 0000 (SDRC point of view).

CS1 start address is programmable and its default value is :

- 0x2000 0000 from a SDRC address point of view
- 0xA000 0000 from a global memory space point of view.

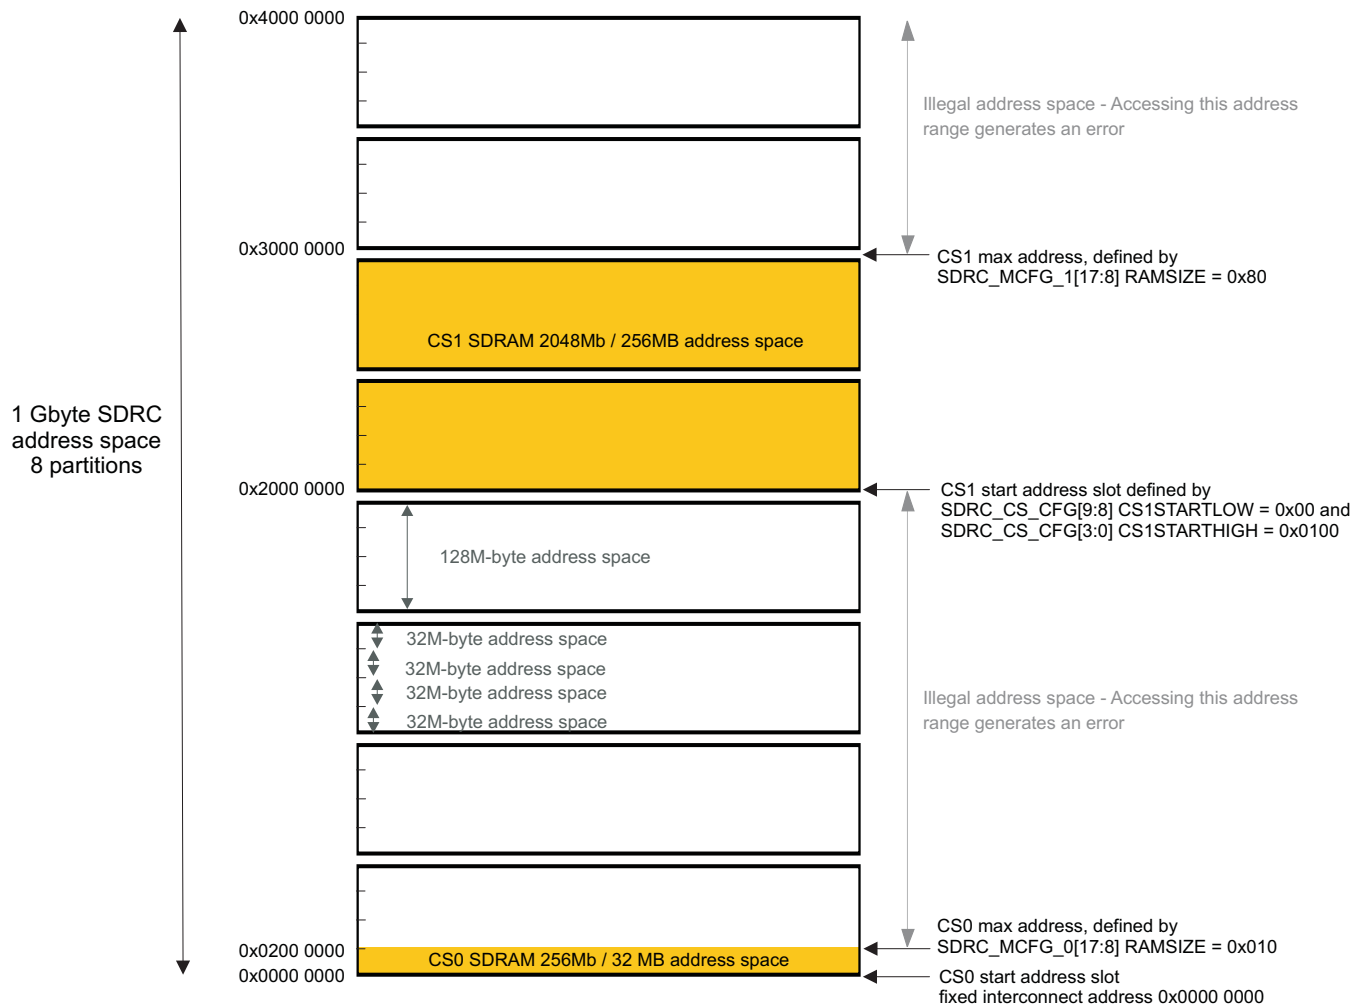

The SDRC 1 Gbyte address space is segmented into eight 128 MBytes address spaces, which are themselves segmented into four 32 Mbytes address spaces, so that 32 possible CS1 start address locations are defined as depicted in [Figure 1-83](#). Note that the first 32 MBytes address space of the first 128 MBytes address space is reserved to CS0 (address 0x0000 0000). Any other address can be used as CS1 start address. To define a CS1 start address, set SDRC\_CS\_CFG[9:8] CS1STARTLOW and SDRC\_CS\_CFG[3:0] CS1STARThigh fields as follow:

- SDRC\_CS\_CFG[3:0] CS1STARThigh corresponds to one of the eight 128 MBytes address spaces (total address space of SDRC is 1 GByte): 0x0000 for the first partition up to 0x0111 for the eighth partition. Note that SDRC\_CS\_CFG[3] must always be set at 0.
- SDRC\_CS\_CFG[9:8] CS1STARTLOW corresponds, for a given 128 MBytes address space, to one of the four 32 MBytes address spaces: 0x00 for the first up to 0x11 for the fourth.

Hence, to have a start address of 0x2000 0000 (SDRC point of view) when connecting a 2048 Mbits SDRAM memory (64M × 32 such as in MUX25, [Table 1-63](#)), SDRC\_CS\_CFG[9:8] CS1STARTLOW must be set to 0x00 (first 32 MBytes address space as depicted in [Figure 1-83](#)) and SDRC\_CS\_CFG[3:0] CS1STARHIGH must be set to 0x0100 (fourth 128 MBytes address space). Note that the start address must be aligned on the memory size.

The CS1 end address (0x3000 0000) can be deduced from the CS1 size, that is from the RAMSIZE parameter, which take the value 0x80 when connecting a 2048 Mbits SDRAM memory.

**Figure 1-83. CS Start and End Address Configuration Example**

sdr-041

## 1.2.7 SDRAM Memory Scheduler (SMS) Registers

Table 1-83 shows the base address and address space for the SMS module instances.

**Table 1-83. SMS Instance Summary**

Module Name	Base Address	Size
SMS	0x6C00 0000	64 Kbytes

3	SOFTRESETLOCK	Soft reset lock bit 0x0: The SMS soft reset can be triggered with any access 0x1: The SMS soft reset can be triggered only with secure supervisor accesses. When this bit is set to 1, a non secure soft reset has no effect on SMS module	RW	0x- <sup>(1)</sup>
2	ERRORREGSLOCK	Error registers lock bit 0x0: The SMS_ERR_TYPE and SMS_ERR_ADDR registers can be read and cleared with any access 0x1: The SMS_ERR_TYPE and SMS_ERR_ADDR registers can be read and cleared only with secure supervisor accesses	RW	0x- <sup>(1)</sup>
1	FIREWALLLOCK	All security firewall registers lock bit 0x0: The SMS firewall registers can be programmed and read with any access 0x1: The SMS firewall registers can be programmed and read only with secure supervisor accesses	RW	0x- <sup>(1)</sup>
0	SECURITYCONTROLREGLOCK	SMS_SECURITY_CONTROL register configuration lock bit 0x0: The SMS_SECURITY_CONTROL register is unlocked 0x1: The SMS_SECURITY_CONTROL register is locked to secure supervisor access only. Only a secure supervisor access or component reset can reset this bit to 0	RW	0x- <sup>(1)</sup>

<sup>(1)</sup> Reset value exported from control module

### 1.2.7.2.9 SMS\_CLASS\_ARBITER0

**Table 1-93. SMS\_CLASS\_ARBITER0**

Address Offset		0x0000 0150																														
Physical Address		0x6C00 0150															InstanceSMS															
Description		This register controls the arbitration parameters between the class 0 request groups.																														
Type		RW																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
BURST-COMPLETE		RESERVED						EXTENDEDGRANT		RESERVED														HIGHPRIOVECTOR		RESERVED						

Bits	Field Name	Description	Type	Reset
31:30	BURST-COMPLETE	Delayed service until burst request complete BurstComplete[k], k= 6 to 7 (BURST-COMPLETE[30] is for group number 6, BURST-COMPLETE[31] is for group number 7)  0x0: Group #k request to arbiter issued as soon as the first burst request is available  0x1: Group #k request to arbiter delayed until a complete burst transaction is buffered	RW	0x0
29:24	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
23:20	EXTENDEDGRANT	Extended grant service inside a class Vector specifying the number of consecutive services a group is granted. 2 bits per group ExtendedGrant[2*k+1,2*k], k = 6 to 7 (EXTENDEDGRANT[21:20] is for group number 6, EXTENDEDGRANT[23:22] is for group number 7)  0x1: 1 service for group #k when granted 0x2: 2 services for group #k when granted 0x3: 3 services for group #k when granted	RW	0x5
19:8	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000
7:6	HIGHPRIOVECTOR	High-priority attribute inside a class Vector allocating a higher priority to one of the class members. A single group may be given this attribute at a time. HighPrioVector[k], k= 6 to 7 (HIGHPRIOVECTOR[6] is for group number 6, HIGHPRIOVECTOR[7] is for group number 7)  0x0: Group #k has standard priority (LRU based). 0x1: Group #k has the highest priority over all other class members.	RW	0x0
5:0	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00

### 1.2.7.2.10 SMS\_CLASS\_ARBITER1

**Table 1-94. SMS\_CLASS\_ARBITER1**

Address Offset		0x0000 0154																Instance		SMS									
Physical Address		0x6C00 0154																											
Description		This register controls the arbitration parameters between the class 1 request groups.																											
Type		RW																											

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								BURST-COMPLETE	RESERVED								EXTENDEDGRANT				RESERVED								HIGHPRIOVECTOR		

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
25:24	BURST-COMPLETE	Delayed service until burst request complete BurstComplete[k], k= 0 to 1 (BURST-COMPLETE[24] is for group number 0, BURST-COMPLETE[25] is for group number 1)  0x0: Group #k request to arbiter issued as soon as the first burst request is available  0x1: Group #k request to arbiter delayed until a complete burst transaction is buffered	RW	0x0
23:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000
11:8	EXTENDEDGRANT	Extended grant service inside a class Vector specifying the number of consecutive services a group is granted. 2 bits per group ExtendedGrant[2*k+1,2*k], k = 0 to 1 (EXTENDEDGRANT[9:8] is for group number 0, EXTENDEDGRANT[11:10] is for group number 1)  0x1: 1 service for group #k when granted  0x2: 2 services for group #k when granted  0x3: 3 services for group #k when granted	RW	0x5
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1:0	HIGHPRIOVECTOR	High-priority attribute inside a class Vector allocating a higher priority to one of the class members. A single group may be given this attribute at a time. HighPrioVector[k], k= 0 to 1 (HIGHPRIOVECTOR[1] is for group number 1, HIGHPRIOVECTOR[0] is for group number 0)  0x0: Group #k has standard priority (LRU based).  0x1: Group #k has the highest priority over all other class members.	RW	0x0

### 1.2.7.2.11 SMS\_CLASS\_ARBITER2

**Table 1-95. SMS\_CLASS\_ARBITER2**

Address Offset		0x0000 0158																													
Physical Address		0x6C00 0158								Instance				SMS																	
Description		This register controls the arbitration parameters between the class 2 request groups.																													
Type		RW																													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<b>Bits</b>	<b>Field Name</b>	<b>Description</b>	<b>Type</b>	<b>Reset</b>											
31:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000000											
4:0	NOFSERVICES	Number of RE split transactions serviced consecutively when the thread gets granted by the arbitration logic.	RW	0x01											

### 1.2.7.2.14 SMS\_ERR\_ADDR

**Table 1-98. SMS\_ERR\_ADDR**

<b>Address Offset</b>	0x0000 0170																														
<b>Physical Address</b>	0x6C00 0170															<b>Instance</b>	SMS														
<b>Description</b>	This register captures the address of an access that has generated an error.																														
<b>Type</b>	R																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ERRORADDRESS																															
<b>Bits</b>		<b>Field Name</b>		<b>Description</b>																		<b>Type</b>		<b>Reset</b>							
31:0		ERRORADDRESS		Access address that has generated an error (bit 31 is always 0)																		R		0x00000000							

### 1.2.7.2.15 SMS\_ERR\_TYPE

**Table 1-99. SMS\_ERR\_TYPE**

<b>Address Offset</b>	0x0000 0174	<b>Instance</b>	SMS
<b>Physical Address</b>	0x6C00 0174		
<b>Description</b>	This register provides additional information about the access that has generated the error.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
RESERVED							ERRORREGIONID	RESERVED	ERRORMCMD					ERRORCONNID					RESERVED					UNEXPECTEDADD	UNEXPECTEDREQ	ILLEGALCMD	RESERVED				ERRORSECOVERLAP	ERRORSECREG	ERRORSECURITY	ERRORVALID

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
26:24	ERRORREGIONID	ID of the region that has been illegally accessed 0x0: Region 0 0x1: Region 1 ... 0x7: Region 7 0x8 to 0xF: reserved	R	0x0
23	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
22:20	ERRORMCMD	Interconnect command that caused the error	R	0x0
19:16	ERRORCONNID	Identifies the illegal access initiator interconnect ConnID of the illegal access initiator. Refer to the top level documentation of the device using the SMS module	R	0x0
15:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
10	UNEXPECTEDADD	Request targeting non-defined rotation contexts (such as contexts 12, 13, 14, or 15) or non-defined L3 Interconnect request signals used for context number decoding.  Read 0x0: No unexpected request received Write 0x0: No effect  Read 0x1: A request has been received on the interconnect with address decoding targeting rotation contexts 12, 13, 14, or 15, or a signal used for context number decoding was undefined. Write 0x1: Clear UNEXPECTEDADD bit.	RW	0x0
9	UNEXPECTEDREQ	Unexpected request received during SMS idle state  Read 0x0: No unexpected request received Write 0x0: No effect  Read 0x1: A request has been received on the interconnect after the SMS was put in idle mode by the system power manager. Write 0x1: Clear the UNEXPECTEDREQ bit field.	RW	0x0
8	ILLEGALCMD	Illegal command on the L3 interface  Read 0x0: No illegal command received Write 0x0: No effect  Read 0x1: Illegal command has been received. Write 0x1: Clear ILLEGALCMD bit field.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:4	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
3	ERRORSECOVERLAP	Protection region overlapping error Read 0x0: No overlap violation detected Write 0x0: No effect Read 0x1: A protection region overlap violation has been detected. Write 0x1: Clear ERRORSECOVERLAP bit field.	RW	0x0
2	ERRORSECREG	SMS security register accessed by nonsecure write transaction Read 0x0: No violation detected on secure registers Write 0x0: No effect Read 0x1: A nonsecure write access to the security control registers has been detected. Such writes are not allowed (reads are always allowed). 0x1: Clear ERRORSECREG bit field	RW	0x0
1	ERRORSECURITY	Security violation error Read 0x0: No illegal command received Write 0x0: No effect Read 0x1: Security violation detected Write 0x1: Clear ERRORSECURITY bit field.	RW	0x0
0	ERRORVALID	Error validity status - Must be explicitly cleared with a write transaction Read 0x0: No effect Write 0x0: All error fields no longer valid Read 0x1: Error detected and logged in the other error fields Write 0x1: Clear ERRORVALID bit field	RW	0x0

### 1.2.7.2.16 SMS\_POW\_CTRL

**Table 1-100. SMS\_POW\_CTRL**

Address Offset	0x0000 0178																Instance								SMS							
Physical Address	0x6C00 0178																															
Description	This register controls the SMS power management in conjunction with the regular interconnect socket registers.																															
Type	RW																															
31 30 29 28 27 26 25 24								23 22 21 20 19 18 17 16								15 14 13 12 11 10 9 8								7 6 5 4 3 2 1 0								
RESERVED																								IDLEDELAY								
Bits	Field Name		Description																								Type		Reset			
31:8	RESERVED		Write 0s for future compatibility. Read returns 0s.																								RW		0x000000			
7:0	IDLEDELAY		Delay (expressed in L3 clock cycle units) before autoidle, that is, before disabling the SMS functional clock when no more traffic in the SMS module.																								RW		0x80			

### 1.2.7.2.17 SMS\_ROT\_CONTROLn

**Table 1-101. SMS\_ROT\_CONTROLn**

<b>Address Offset</b>	0x0000 0180 + (0x0000 0010 * n)	<b>Index</b>	n = 0 to 11																												
<b>Physical Address</b>	0x6C00 0180 + (0x0000 0010 * n)	<b>Instance</b>	SMS																												
<b>Description</b>	This register configures the virtual rotated frame buffer module for context #n.																														
<b>Type</b>	RW																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																PH		RESERVED	PW		RESERVED	PS									

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10:8	PH	Exponent based 2 value, 2 <sup>ph</sup> indicates the page height in bytes for context #n.	RW	0x0
7	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
6:4	PW	Exponent based 2 value, 2 <sup>pw</sup> indicates the page width in bytes for context #n.	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1:0	PS	Exponent based 2 value, 2 <sup>ps</sup> indicates the pixel size in bytes for context #n. A value of 3 is invalid.	RW	0x0

### 1.2.7.2.18 SMS\_ROT\_SIZE<sub>n</sub>

**Table 1-102. SMS\_ROT\_SIZE<sub>n</sub>**

<b>Address Offset</b>	0x0000 0184 + (0x0000 0010 * n)	<b>Index</b>	n = 0 to 11
<b>Physical Address</b>	0x6C00 0184 + (0x0000 0010 * n)	<b>Instance</b>	SMS
<b>Description</b>	This register configures the bank organization for context #n.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								IMAGEHEIGHT								RESERVED								IMAGEWIDTH							

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
26:16	IMAGEHEIGHT	Image height in pixels for context #n	RW	0x000
15:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
10:0	IMAGEWIDTH	Image width in pixels for context #n	RW	0x000

### 1.2.7.2.19 SMS\_ROT\_PHYSICAL\_BA<sub>n</sub>

**Table 1-103. SMS\_ROT\_PHYSICAL\_BA<sub>n</sub>**

<b>Address Offset</b>	0x0000 0188 + (0x0000 0010 * n)	<b>Index</b>	n = 0 to 11
<b>Physical Address</b>	0x6C00 0188 + (0x0000 0010 * n)	<b>Instance</b>	SMS
<b>Description</b>	This register allows to configure the physical base address for context #n.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	PHYSICALBA																														

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
30:0	PHYSICALBA	Physical base address of the frame buffer for context #n in SDRAM	RW	0x00000000

## 1.2.8 SDRC Registers

Table 1-104 shows the base address and address space for the SDRC module instances.

**Table 1-104. SDRC Instance Summary**

Module Name	Base Address	Size
SDRC	0x6D00 0000	64 Kbytes

### 1.2.8.1 SDRC Register Mapping Summary

Table 1-105 summarizes the SDRC register mapping.

**Table 1-105. SDRC Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address	Section
SDRC_SYSCONFIG	RW	32	0x0000 0010	0x6D00 0010	<a href="#">Section 1.2.8.2.1</a>

RESERVED																CS1STARTLOW	RESERVED	CS1STARHIGH													

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x000000
9:8	CS1STARTLOW	CS1 address space start address (lower add bits a1:a0) / 32MB unit	RW	0x0
7:4	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x0
3:0	CS1STARHIGH	CS1 address space start address (upper add bits a5:a4:a3:a2) / 128MB unit	RW	0x4

### 1.2.8.2.4 SDRC\_SHARING

**Table 1-109. SDRC\_SHARING**

<b>Address Offset</b>		0x0000 0044																<b>Instance</b>		SDRC															
<b>Physical Address</b>		0x6D00 0044																																	
<b>Description</b>		This register specifies the SDRC attached memory size and position on the SDRC I/Os.																																	
<b>Type</b>		RW																																	
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
RESERVED	LOCK	RESERVED														CS1MUXCFG				CS0MUXCFG				SDRCTRISTATE	RESERVED										
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>																<b>Type</b>								<b>Reset</b>									
31	RESERVED	Write 0s for future compatibility. Read returns 0.																RW								0x0									
30	LOCK	Read-only access lock bit  0x0: This register is fully writable.  0x1: When this bit is set, the register can not be un-set until next reset of the module.																RW								See <sup>(1)</sup>									
29:15	RESERVED	Write 0s for future compatibility. Read returns 0s.																RW								See <sup>(1)</sup>									
14:12	CS1MUXCFG	Identifies the SDRC pins used by CS1 0x0: 32-bit SDRAM on Datalane[31:0] 0x1: 32-bit SDRAM on Datalane[31:0] 0x2: 16-bit SDRAM on Datalane[31:16] 0x3: 16-bit SDRAM on Datalane[16:0] 0x4: Reserved 0x5: Reserved 0x6: Reserved 0x7: 16-bit SDRAM on Datalane[31:16]																RW								See <sup>(1)</sup>									
11:9	CS0MUXCFG	Identifies the SDRC pins used by CS0 0x0: 32-bit SDRAM on Datalane[31:0] 0x1: 32-bit SDRAM on Datalane[31:0] 0x2: 16-bit SDRAM on Datalane[31:16] 0x3: 16-bit SDRAM on Datalane[16:0] 0x4: Reserved 0x5: Reserved 0x6: Reserved 0x7: 16-bit SDRAM on Datalane[31:16]																RW								See <sup>(1)</sup>									
8	SDRCTRISTATE	Static 3-state command for the SDRC I/O pads  0x0: All SDRC interface pins are set to hi-Z.  0x1: Normal mode: SDRC drives the I/O pads based on the memory traffic.																RW								See <sup>(1)</sup>									
7:0	RESERVED	Write 0s for future compatibility. Read returns 0s.																RW								See <sup>(1)</sup>									

<sup>(1)</sup> Reset value is copied from the system control module. See the note in [Section 1.2.5.3.2](#) and in the *Secure SDRC Registers* section of the *System Control Module* chapter.

### 1.2.8.2.5 SDRC\_ERR\_ADDR

**Table 1-110. SDRC\_ERR\_ADDR**

<b>Address Offset</b>	0x0000 0048																																																																																														
<b>Physical Address</b>	0x6D00 0048															<b>Instance</b> SDRC																																																																															
<b>Description</b>	This register captures the address of the last illegal access received on the interconnect.

RESERVED																ERRORCONNID				RESERVED	ERRORMCMD			ERRORADD		ERRORDPD	ERRORVALID																																																																
Bits	Field Name	Description																Type	Reset																																																																								
31:12	RESERVED	Write 0s for future compatibility. Reads return 0s.																RW	0x00000																																																																								
11:8	ERRORCONNID	Identifies the interconnect ConnID of the illegal access initiator: Refer to the top level documentation of the device using the SDRC module.																RW	0x0																																																																								
7	RESERVED	Write 0 for future compatibility. Reads return 0.																RW	0x0																																																																								
6:4	ERRORMCMD	System command of the transaction that caused the error (3-bit field)																RW	0x0																																																																								
3:2	ERRORADD	Flag that indicates access is to an illegal address																RW	0x2																																																																								
		Read 0x0: The system request was to an address outside the memory space.																																																																																									
		Write 0x0: Clear ErrorAdd bit field.																																																																																									
		Read 0x1: The system request was to an address outside the register space.																																																																																									
		Write 0x1: No effect																																																																																									
		Read 0x2: No Err Add. Not an address error																																																																																									
		Write 0x2: No effect																																																																																									
		Read 0x3: No Err Add. Not an address error																																																																																									
		Write 0x3: No effect																																																																																									
1	ERRORDPD	Transaction error while the memory is in deep-power-down mode																RW	0x0																																																																								
		0x0: The memory was not in deep-power-down mode when the error occurred.																																																																																									
		0x0: No effect																																																																																									
		0x1: The error is due to an unexpected access while the memory was in deep-power-down mode.																																																																																									
		0x1: Clear the ErrorDPD bit field.																																																																																									
0	ERRORVALID	Error validity status - Must be explicitly cleared with a write 0 transaction.																RW	0x0																																																																								
		0x0: All error fields no longer valid																																																																																									
		0x0: Clear ErrorValid bit field																																																																																									
		0x1: Error detected and logged in the other error fields																																																																																									
		0x1: No effect																																																																																									

### 1.2.8.2.7 SDRC\_DLLA\_CTRL

**Table 1-112. SDRC\_DLLA\_CTRL**

<b>Address Offset</b>	0x0000 0060	<b>Instance</b>	SDRC
<b>Physical Address</b>	0x6D00 0060		
<b>Description</b>	This register controls the SDRC DLL A resource used for fine timing tuning on a double-data-rate interface.		
<b>Type</b>	RW		
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
FIXEDDELAY	MODEFIXEDDELAYINITLAT	RESERVED	WRITEDDRCLKX2DIS DLLMODEONIDLEREQ DLLIDLE ENADLL LOCKDLL DLLPHASE RESERVED

Bits	Field Name	Description	Type	Reset
31:24	FIXEDDELAY	Phase offset value in ModeFixedDelay mode. Maximum frequency supported in this mode is 83 MHz. FIXEDDELAY steps are defined after DLL cell characterization.	RW	0x00
23:16	MODEFIXEDDELAYINITLAT	Initial latency before first request to be processed in ModeFixedDelay mode <sup>(1)</sup> 0x0: no initial latency before first access 0x1: 2 clock cycles before first access 0x2: 4 clock cycles before first access 0x3: 6 clock cycles before first access 0x4 : 8 clock cycles before first access ... 0xFF: 510 clock cycles before first access	RW	0x00
15:8	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x00
7	WRITEDDRCLKX2DIS	Disable MDDR write path using the double frequency input clock.  0x0: MDDR write path using the double frequency clock logic 0x1: MDDR write path using the DLL/CDL write path logic	RW	0x0
6:5	DLLMODEONIDLEREQ	Selects the DLL mode upon hardware idle request  0x0: DLL in Power-down mode upon hardware idle request 0x1: DLL in DLL idle mode upon hardware idle request 0x2: No action upon hardware idle request. Input clock frequency must not be changed. 0x3: Reserved for future use (no action upon hardware idle request).	RW	0x0
4	DLLIDLE	Enables the CQ0040v1 DLL Idle mode  0x0: DLL Idle mode disabled 0x1: DLL Idle mode enabled	RW	0x0
3	ENADLL	Enables DLL  0x0: DLL disabled 0x1: DLL enabled	RW	0x0

<sup>(1)</sup> The DLL characterization shows that this feature is not useful and that this value shall be left at 0x0.

Bits	Field Name	Description	Type	Reset
2	LOCKDLL	<p>Selects the DLL functionality between the TrackingDelay mode (previously called lock mode) or the ModeFixedDelay mode (previously called unlock mode). The DLL mode is updated in the DLL cell after:</p> <ul style="list-style-type: none"> <li>- DLLIDLE mode</li> <li>- DLL power-down mode</li> </ul> <p>0x0: LOCKDLL at 0 puts the DLL in TrackingDelay mode (tracking counter started).</p> <p>0x1: LOCKDLL at 1 puts the DLL in ModeFixedDelay mode. The fixed delay defined in FIXEDDELAY bit field is used to delay DQS lines for read accesses.</p>	RW	0x0
1	DLLPHASE	<p>Nominal digitally controlled delay when DLL is enabled</p> <p>Recommendation to use a 72-degree DLL phase for read accesses and 90-degree DLL phase for write accesses.</p> <p>0x0: 72 degrees (20% of the clock period)</p> <p>0x1: 90 degrees (25% of the clock cycle)</p>	RW	0x0
0	RESERVED	Write 0s for future compatibility. Reads return zero.	RW	0x0

### 1.2.8.2.8 SDRC\_DLLA\_STATUS

**Table 1-113. SDRC\_DLLA\_STATUS**

Address Offset	0x0000 0064																																																																																													
Physical Address	0x6D00 0064																Instance	SDRC

1	RESERVED		Reads return zero.																												R		0x0																																																													
0	RESERVED		Reads return zero.																												R		0x0																																																													

### 1.2.8.2.9 SDRC\_POWER\_REG

**Table 1-114. SDRC\_POWER\_REG**

Address Offset		0x0000 0070																Instance		SDRC									
Physical Address		0x6D00 0070																											
Description		The SDRC power management register defines the global power management policy (shared by CS0/CS1).																											
Type		RW																											

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED					WAKEUPPROC	RESERVED	AUTOCOUNT										SRFRONRESET	SRFRONIDLEREQ	CLKCTRL	EXTCLKDIS	PWDENA	RESERVED	PAGEPOLICY								

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x00
26	WAKEUPPROC	Select if after a SDRC wake-up in DDR mode (in DLL TrackingDelay mode), the first request is stalled during 500 cycles latency or until the lock signal from the DLL/CDL analog cell is asserted.  0x0: SDRC allows DDR access after 500 L3 clock cycles 0x1: SDRC allows DDR access as soon as DLL LOCKSTATUS bit is 1	RW	0x0
25:24	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x0
23:8	AUTOCOUNT	16-bit programmable count value used for delayed automatic clock gating and self-refresh entry, assuming CLKCTRL field is not 0	RW	0x0000
7	SRFRONRESET	Enter self refresh when a warm reset is applied:  0x0: Feature disabled 0x1: Feature enabled	RW	0x1
6	SRFRONIDLEREQ	Enter self refresh when on hardware idle request:  0x0: Feature disabled 0x1: Feature enabled	RW	0x0
5:4	CLKCTRL	Clock control feature defines clock gating and self refresh:  0x0: No auto clk feature turned on 0x1: Enable internal clock gating on timeout of Auto_cnt 0x2: Enable self-refresh on timeout of Auto_cnt 0x3: Reserved	RW	0x0
3	EXTCLKDIS	Disable the clock provided to the external memories:  0x0: Enable clock 0x1: Disable clock- Logical 0 is applied.	RW	0x0
2	PWDENA	Activate the power-down mode of the target memory through CKE pin.  0x0: Power-down mode feature disabled 0x1: Power-down mode feature enabled	RW	0x1
1	RESERVED	Write 0 for future compatibility. Read returns 0.	RW	0x0
0	PAGEPOLICY	Page/segment closure policy with respect to power versus bandwidth trade-off - Must be set to 1  0x0: Reserved - must not be used 0x1: High-power/high bandwidth mode (HPHB)	RW	0x1

### 1.2.8.2.10 SDRC\_MCFG\_p

**Table 1-115. SDRC\_MCFG\_p**

<b>Address Offset</b>	0x0000 0080 + (0x0000 0030 * p)	<b>Index</b>	p = 0 to 1
<b>Physical Address</b>	0x6D00 0080 + (0x0000 0030 * p)	<b>Instance</b>	SDRC
<b>Description</b>	This register provides the memory configuration register.		
<b>Type</b>	RW		

### 1.2.8.2.11 Register Description for ADDRMUXLEGACY = 0x1

#### Register Description for ADDRMUXLEGACY = 0x1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	LOCKSTATUS	RESERVED			RASWIDTH			RESERVED	CASWIDTH			ADDRMUXLEGACY	RESERVED	RAMSIZE												BANKALLOCATION	RESERVED	B32NOT16	DEEPPD	DDRTYPE	RAMTYPE

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Reads return 0.	RW	0x0
30	LOCKSTATUS	Read-only access lock bit 0x0: This register is fully writable 0x1: When this bit is set, the register can not be un-set until next reset of the module.	RW	See <sup>(1)</sup>
29:27	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	See <sup>(1)</sup>
26:24	RASWIDTH	RAS address width 0x0: RAS width = 11 bits 0x1: RAS width = 12 bits 0x2: RAS width = 13 bits 0x3: RAS width = 14 bits 0x4: RAS width = 15 bits 0x5: RAS width = 16 bits - Must not be used 0x6: RAS width = 17 bits - Must not be used 0x7: RAS width = 18 bits - Must not be used	RW	See <sup>(1)</sup>
23	RESERVED	Write 0s for future compatibility. Reads return 0.	RW	See <sup>(1)</sup>

### 1.2.8.2.13 SDRC\_MR\_p

**Table 1-116. SDRC\_MR\_p**

<b>Address Offset</b>	0x0000 0084 + (0x0000 0030 * p)	<b>Index</b>	p = 0 to 1
<b>Physical Address</b>	0x6D00 0084 + (0x0000 0030 * p)	<b>Instance</b>	SDRC
<b>Description</b>	This 12-bit register corresponds to the JEDEC SDRAM MR register, with the standard bit fields. All 12 bits are loaded into memory for future extension support. The SDRC keeps an internal copy register used internally; that is, returned when a read access is performed at that address. Load into memory on interconnect write access using MRS command with BA1,BA0 = 0,0.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ZERO_1		WBST	ZERO_0		CASL			SIL	BL						

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11:10	ZERO_1	Write 0s, as required by memory specifications. Reads return 0s.	RW	0x0
9	WBST	Write burst support must be zero. 0x0: Write burst equals read burst 0x1: Write burst disable (single write access only)	RW	0x0
8:7	ZERO_0	Write 0s, as required by memory specifications. Read returns 0s.	RW	0x0
6:4	CASL	CAS latency as defined by clock periods 0x1: CAS latency = 1 0x2: CAS latency = 2 0x3: CAS latency = 3 0x4: CAS latency = 4 0x5: CAS latency = 5	RW	0x2

### 1.2.8.2.14 SDRC\_EMR2\_p

**Table 1-117. SDRC\_EMR2\_p**

<b>Address Offset</b>	0x0000 008C + (0x0000 0030 * p)																<b>Index</b>	p = 0 to 1															
<b>Physical Address</b>	0x6D00 008C + (0x0000 0030 * p)																<b>Instance</b>	SDRC															
<b>Description</b>	This 12-bit register corresponds to the low-power EMR register, as defined in the mobile DDR JEDEC Standard. All 12 bits are loaded into the memory, thus assuring future extension support. The SDRC keeps an internal copy register used internally; that is, returned when a read access is performed at that address. Load into memory on interconnect write access using MRS command with BA1,BA0 = 1,0.																																
<b>Type</b>	RW

## 1.3 On-Chip Memory (OCM) Subsystem

### 1.3.1 OCM Subsystem Overview

The on-chip memory subsystem consists of two separate on-chip memory controllers, one connected to an on-chip ROM (OCM\_ROM) and the other connected to an on-chip RAM (OCM\_RAM). Each memory controller has its own dedicated interface to the L3 interconnect.

---

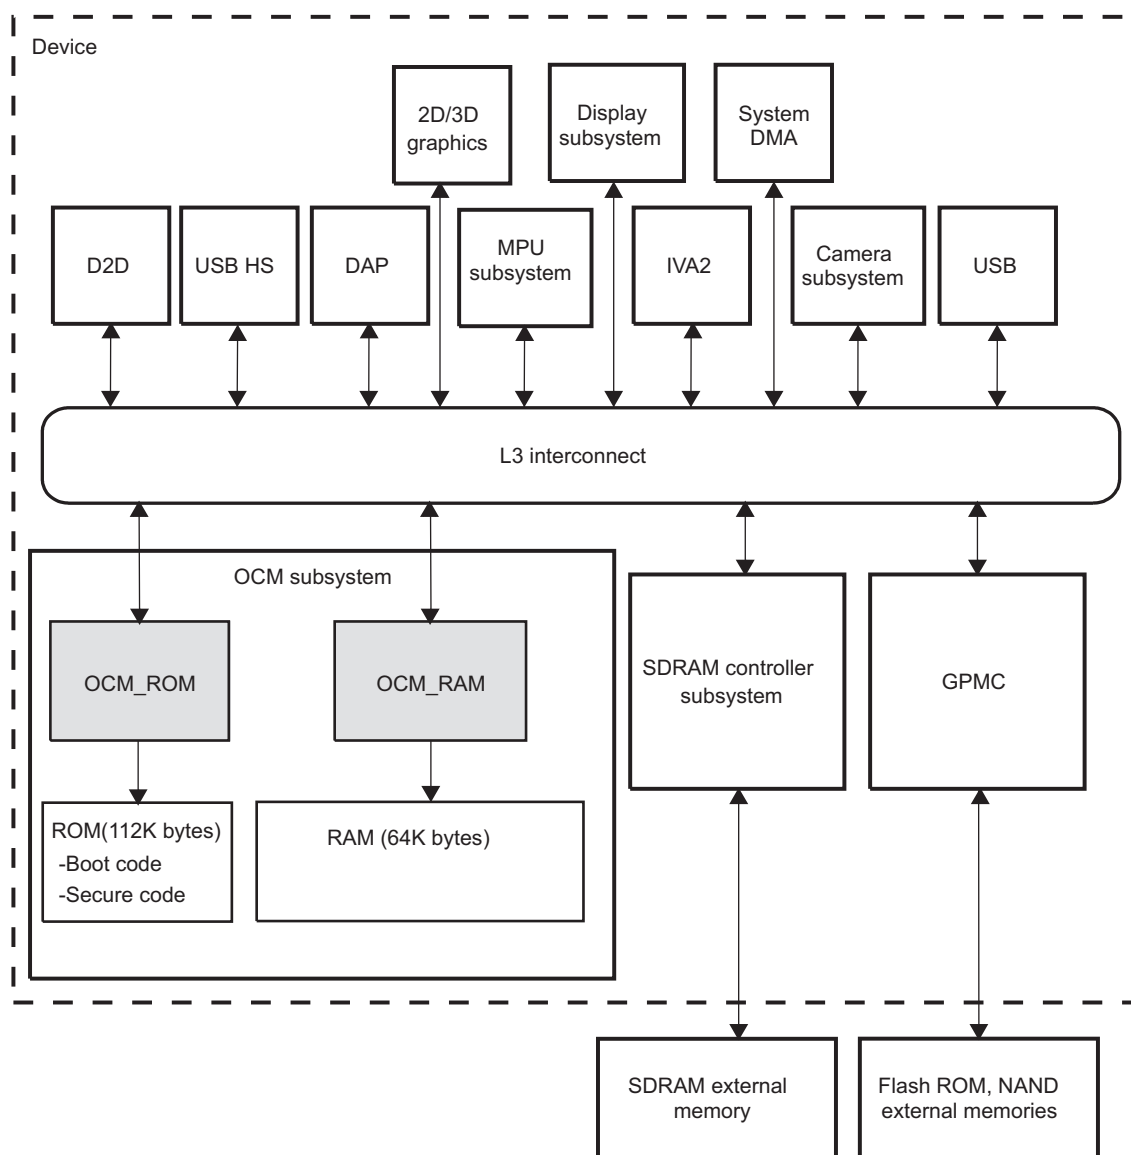

**Note:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

---

Figure 1-84 is an overview of the OCM subsystem.

**Figure 1-84. OCM Subsystem Overview**

ocm-001

Multiple L3 initiators (such as remote devices) have access to the RAM through 2D/3D graphics, the MPU subsystem, sDMA, the camera subsystem, the display subsystem, IVA2, and USB.

ROM is used for direct boot code, boot from external NAND flash, and secure code.

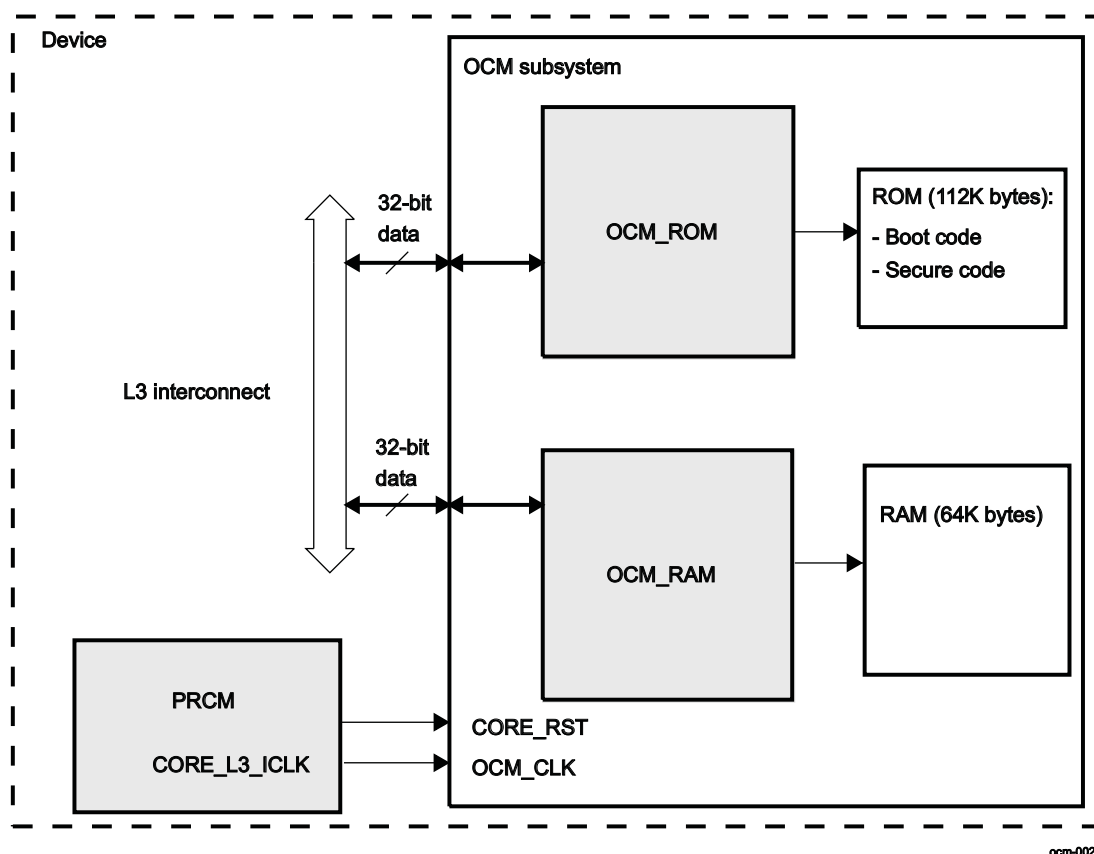

## 1.3.2 OCM Subsystem Integration

### 1.3.2.1 Description

The OCM\_ROM and OCM\_RAM allow transactions between the system initiators and the multiple memories, through the L3 interconnect.

Figure 1-85 shows the integration of the OCM subsystem to the OMAP processor.

Figure 1-85. OCM Subsystem Integration to the Device

ocm-002

### 1.3.2.2 Clocking, Reset, and Power-Management Scheme

#### 1.3.2.2.1 Clocking

The on-chip boot ROM and RAM are clocked only when they are accessed.

The interface clock OCM\_CLK comes from the PRCM module and runs at the L3 interconnect frequency. The OCM\_CLK source is PRCM CORE\_L3\_ICLK output. This clock is also used as the functional clock for the OCM module.

For the OCM subsystem, no register enables the gating of OCM\_CLK.

However, OCM does support the handshaking protocol with the PRCM module. It is not programmable by software. The following signals support the handshaking protocol for ROM and RAM devices:

- OCMROM\_IDLREQ/OCMROM\_SIDLEACK (for ROM devices)
- OCMRAM\_IDLREQ/OCMRAM\_SIDLEACK (for RAM devices)

OCM\_CLK is gated if all modules (including the OCM) belonging to the L3 CLK domain send a SldleAck back to the PRCM module after reception of the MIdleReq request.

For details, see the *Power, Reset, and Clock Management* chapter.

When the memory is not accessed by the system, the module performs automatic clock gating. Because the clock to the memory is dynamically gated, there is no extra latency when the clock must be switched on after an idle state.

#### 1.3.2.2.2 Hardware Reset

Global reset of the module is performed by activation of the CORE\_RST in the core reset domain (see the *Power, Reset, and Clock Management* chapter).

#### 1.3.2.2.3 Power Domain

OCM power is supplied by the CORE power domain (see the *Power, Reset, and Clock Management* chapter).

### 1.3.3 OCM Subsystem Functional Description

#### 1.3.3.1 OCM\_ROM

The embedded ROM is used primarily for booting, flashing, and context restoring.

The device-embedded ROM (total 32K bytes) has the following characteristics:

- The ROM contains the boot area.
- The OCM\_ROM supports single and burst access transactions.
- The OCM\_ROM operates at full interconnect clock frequency.
- The COM\_ROM needs three cycles for initial access and one cycle per subsequent access.

The memory space of the embedded ROM starts at 0x4001 4000 and ends at 0x4001 BFFF.

#### 1.3.3.2 OCM\_RAM

By default, only 2K bytes are nonsecure after reset; however, the configuration can then be changed to adapt to booting/flashing, normal boot, or to any application requirement.

The device-embedded RAM has the following characteristics:

- Operates at full L3 interconnect clock frequency
- Fully pipelined, one 32-bit access per cycle
- Restricted access support, based on:
  - A region-based partitioning (see the L3 firewall description)
  - The module owner of the access, with respect to its read and write permission to that region
  - The transaction attributes of the access, with respect to the region permission properties:
    - Secure/nonsecure
    - User/supervisor
    - Code/data access

The OCM\_RAM can be partitioned using the L3 firewall (see the *Interconnect* chapter) and used as:

- Public RAM for normal RAM, or
- Secure RAM:
  - For secure data and instructions
  - For secure Level 2 data and instruction cache:
    - Secure stack
    - Secure global data
    - Secure heap
    - Secure decrypted applications
    - Crypto keys

The OCM\_RAM can be partitioned using the L3 firewall and used as:

- Public RAM for a video frame buffer
- Secure RAM for a secure video frame buffer
- Secure RAM for computing heavy DRM applications such as real-time video decryption
- Secure RAM for any application

The RAM memory space starts at 0x4020 0000 and ends at 0x4020 FFFF.

## 1.4 Revision History

[Table 1-122](#) lists the changes made since the previous version of this document.

**Table 1-122. Document Revision History**

Reference	Additions/Modifications/Deletions
<a href="#">Table 1-1</a>	Added table note.
<a href="#">Figure 1-42</a>	Changed figure. 1/14/2009 (Check text around figure for accuracy.)
<a href="#">Section 1.1.6.2.2</a>	Changed 5th bullet.
<a href="#">Table 1-61</a>	Added table note.
<a href="#">Section 1.2.2.1</a>	Changed first sentence.
<a href="#">Section 1.2.4.4.3</a>	Added caution.
<a href="#">Section 1.2.4.4.11.1</a>	Changed 2nd and 3rd sentence in 1st paragraph.
<a href="#">Section 1.2.5.3.4</a>	Added last paragraph.
<a href="#">Section 1.2.5.3.4</a>	Added note.
<a href="#">Table 1-112</a>	Changed bit description.

## ***Camera Interface Subsystem (ISP)***

---

---

---

This chapter describes the camera interface subsystem (ISP) in the OMAP35x Applications Processor.

---

**Note:** This chapter describes the camera interface subsystem of the OMAP35x Applications Processor only. The camera subsystem for lower-tier devices will be described in a future version of the TRM.

---

## 1.1 Camera ISP Overview

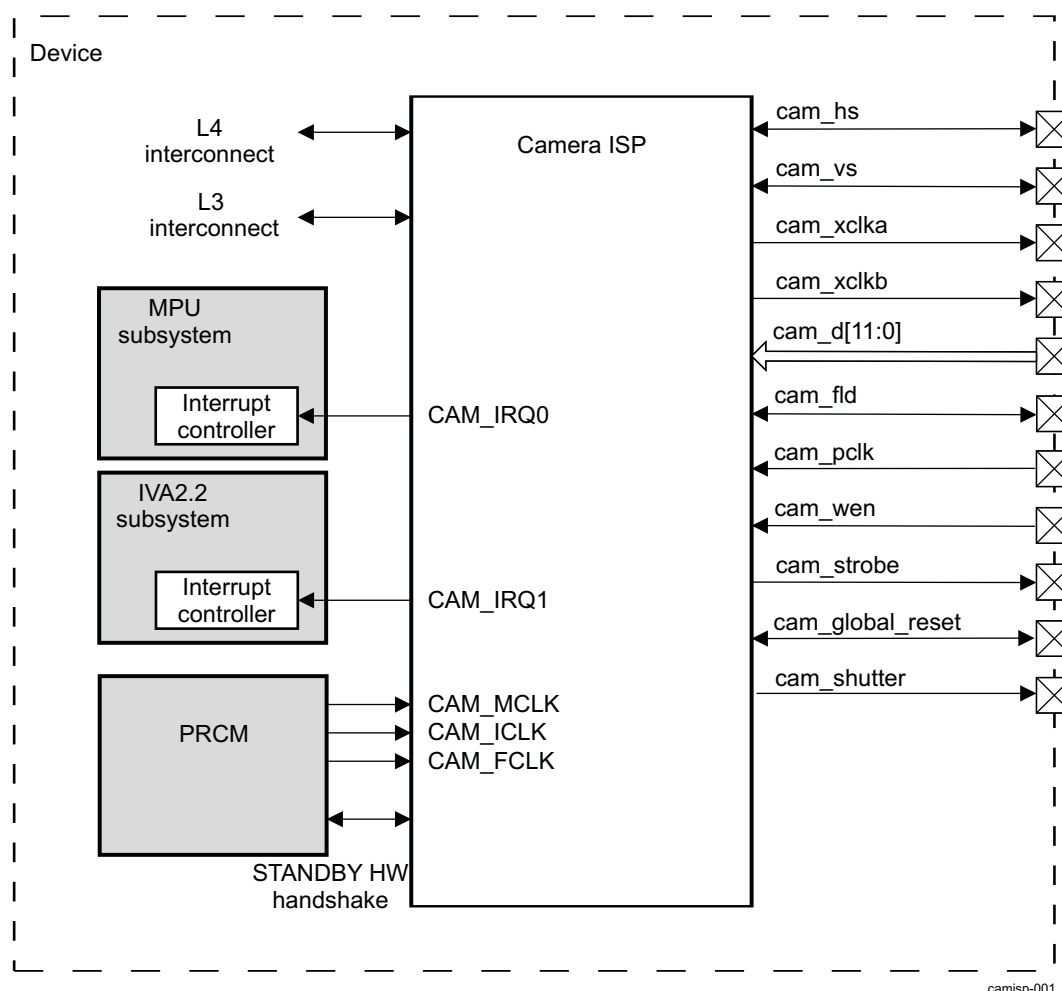

The camera ISP is a key component for imaging and video applications such as video preview, video record, and still-image capture with or without digital zooming.

The camera ISP provides the system interface and the processing capability to connect RAW image-sensor modules to the OMAP35x Applications Processor.

**Note:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

Figure 1-1 shows the camera ISP.

**Figure 1-1. Camera ISP Highlight**

### 1.1.1 Camera ISP Features

The camera ISP can support the following features:

- **Image sensor:**
  - Interface with various image sensors:
    - R, G, B primary colors
    - Ye, Cy, Mg, G complementary colors
  - Support for electronic rolling shutter (ERS) and global-release reset shutters
- **Parallel interface:** The parallel interface supports two modes:
  - **SYNC mode:** In this mode, the image-sensor module provides horizontal and vertical synchronization signals to the parallel interface, along with the pixel clock. This mode works with 8-, 10-, 11-, and 12-bit data (above 10-bit RAW data, the processing pipe cannot be used; data must be transferred to memory). SYNC mode supports progressive and interlaced image-sensor modules.
  - **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. The horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds start-of-active (SAV) and end-of-active video (EAV) synchronization code. This mode works in 8- and 10-bit configurations. It supports only progressive image-sensor modules.

---

**Note:**

- Up to 8-bit data at 130 MHz can be transferred to memory.
  - Up to 10-bit data at 75 MHz can be processed by the image pipeline or transferred to memory.
  - Up to 12-bit data at 75 MHz can be transferred to memory as is, or after processing inside the CCDC. It can also be internally converted to 10-bit data for full processing.
- **Video processing:** The video-processing hardware removes the need for expensive camera modules to perform processing functions. The hardware pipeline contains two parts: front end and back end:
  - **CCDC:** Performs signal-processing operations on RAW image input data. The output data can go directly to memory for software processing, or to IPIPE for further processing. Signal-processing operations include:
    - Optical clamping
    - Optical black clamp
    - Black-level compensation
    - Look-up table (LUT) based faulty pixel correction
    - 2D lens-shading compensation
    - Data formatter
    - Output formatter
  - **IPIPE:** Performs signal-processing operations on RAW image input data. Outputs YCbCr 4:2:2 data.
    - **Preview module:** Signal-processing operations include:
      - A-law decompression: transforms non-linear 8-bit data to 10-bit linear data. The CCDC module can perform A-law compression
      - Noise reduction and faulty pixel correction
        - Dark frame capture and subtraction
        - Horizontal median filter
        - Programmable filter: 3x3 kernel of the same color
        - Couplet faulty pixel correction
      - Digital gain
      - White balance
      - Programmable color filter array (CFA) interpolation: 5x5 kernel
      - Black adjustment

- Programmable color correction (RGB to RGB)
  - Programmable gamma correction: 1024 entries for each color
  - Programmable color conversion (RGB to YCbCr 4:4:4)
  - Color subsampling (YCbCr 4:4:4 to YCbCr 4:2:2)
  - Luminance enhancement (non-linear), chrominance suppression and offset
- The preview module can also work from memory to memory.
- **Resizer module:** Performs on-the-fly upsampling (up to x4) and downsampling (down to x0.25) of YCbCr 4:2:2 data by applying high-quality horizontal and vertical filters. The horizontal and vertical resizer ratios are independent. Applicable ratios are 256/N, with N ranging from 64 to 1024. This feature enables digital zooming (upsampling) and video preview (downsampling). The resizer module can also work from memory to memory. Higher or lower ratios can be obtained by combining on-the-fly resizing followed by memory-to-memory resizing.
  - **Statistic collection modules (SCM):** The host CPU uses statistics to adjust various parameters for processing image data.
    - **3A metrics:** Collects on-the-fly RAW image data metrics, which are required to perform the control loops for auto white balance (AWB), auto exposure (AE), and autofocus (AF). The MPU subsystem typically uses data metrics to adjust various parameters for processing image data.
    - **Histogram:** Performs on-the-fly pixel binning of RAW image, based on color value ranges and regions. Supports up to 4 regions and up to 256 bins per color. The MPU subsystem typically uses the histogram with 3A metrics to adjust various parameters for processing image data.

The histogram module can also work from memory to memory.
  - **Central-resource shared buffer logic (SBL):** Buffers and schedules memory accesses requested by camera ISP modules
  - **Circular buffer:** Prevents storage of full image frames in memory when data must be postprocessed and/or preprocessed by software
  - **Memory management unit (MMU):** Manages virtual-to-physical address translation for external addresses and solves the memory-fragmentation issue. Enables the camera driver to dynamically allocate and deallocate memory; the MMU handles memory fragmentation.
  - **Clock generator:** Generates two independent clocks that can be used by two external image sensors
  - **Secure mode:** Used to store sensitive captured images
  - **Timing control:**
    - Generation of two clocks that can be used by the external image sensors
    - Generation of signals for strobe flash, mechanical shutter, and global reset. Support for red-eye removal.
  - **Open core protocol (OCP) compliant:**
    - One 64-bit master interface connected to L3
    - One 32-bit slave interface connected to L4

---

**Note:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

---

## 1.2 Camera ISP Environment

### 1.2.1 Camera ISP Functions

Table 1-1 describes the camera ISP functions and the corresponding application fields.

**Table 1-1. Camera ISP Functions**

Function	Description
Parallel interface in generic configuration (SYNC mode)	The camera ISP supports up to 12 bits (Most image-processing pipeline operations support only up to 10 bits; when it is more than 10 bits, some limited capabilities apply to CCDC only). The camera ISP can interface with RAW interlaced or progressive image sensors using RGB or complementary color mosaic filters.
Parallel interface in ITU-R BT.656 configuration (ITU mode)	The camera ISP can extract the synchronization signal start of active video and end of active video from the ITU-R BT.656 bit stream. 8-bit and 10-bit modes are supported.

### 1.2.2 Camera ISP Signal Descriptions

**Table 1-2. I/O Description**

Signal Name	I/O <sup>(1)</sup>	Description	Parallel SYNC Mode	Parallel ITU Mode
cam_hs	I/O	Line trigger input/output signal	+	
cam_vs	I/O	Frame trigger input/output signal	+	
cam_fld	I/O	Field identification input/output signal	+	
cam_pclk	I	Parallel interface pixel clock	+	+
cam_d[11:0]	I	Parallel mode: input data bits 0 to 11	+	+ [9:0] when bridge is not used; [7:0] when bridge is used
cam_wen	I	External write-enable signal	+	
cam_strobe	O	Flash strobe control signal	+	+
cam_shutter	O	Mechanical shutter control signal	+	+
cam_global_reset	I/O	Global reset release shutter signal	+	+
cam_xclka	O	External clock for the image-sensor module	+	+
cam_xclkb	O	External clock for the image-sensor module		

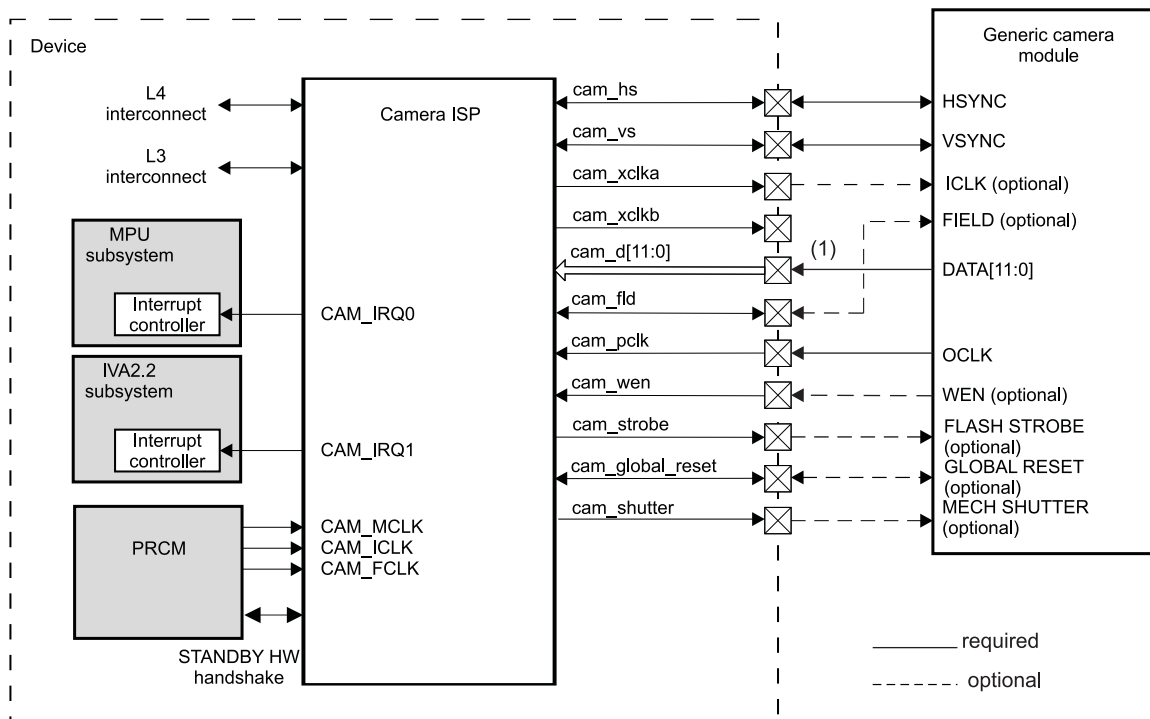

<sup>(1)</sup> I = Input, O = Output, PWR = Power

### 1.2.3 Camera ISP Modes

- Parallel interface in generic configuration

Figure 1-2 shows a block diagram of the parallel interface in generic configuration.

Figure 1-2. Parallel Interface in Generic Configuration

camisp-002

- (1) These signals are muxed. They are controlled by registers CONTROL\_PADCONF\_CAM\_FLD and CONTROL\_PADCONF\_CAM\_D.

#### CAUTION

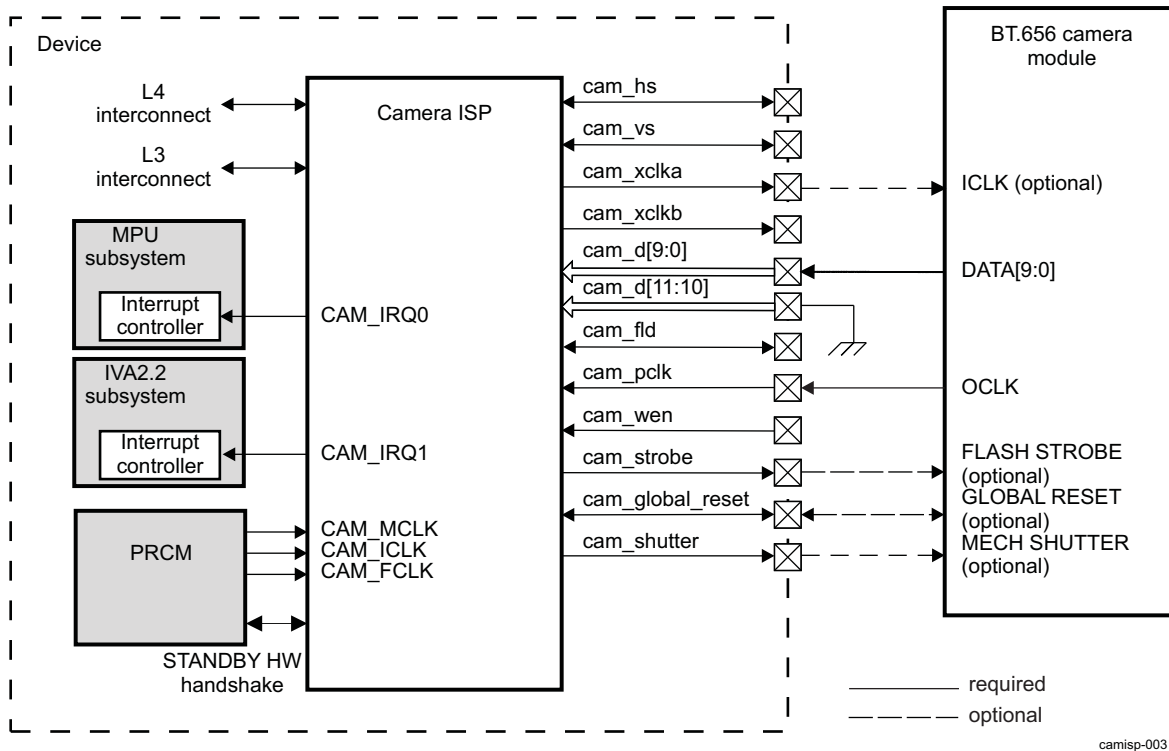

The parallel interface in generic configuration mode works with 8-, 10-, 11-, and 12-bit sensors. 8 to 12 bits refers to data-lane count, not pixel coding. For example, when a video decoder is used, it sends 16 bits per pixel. The data is transmitted through 8 data lanes at x2 pixel clock. The bridge can be used to reassemble the 16-bit pixels.

**Note:** For information about using the data-lane shifter for different configurations, see [Table 1-14](#).

- Parallel interface in ITU-R BT.656 configuration

Figure 1-3 shows a block diagram of the parallel interface in ITU-R BT.656 configuration.

**Figure 1-3. Parallel Interface in ITU-R BT.656 Configuration**

**Note:** For information about using the data-lane shifter for different configurations, see [Table 1-14](#).

## 1.2.4 Camera ISP Protocols and Data Formats

### 1.2.4.1 Parallel Generic Configuration Protocol and Data Format (8, 10, 11, 12 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8 to 14-bit-wide data signals.

In this configuration, no assumptions are made on the data format of pixels, but the dynamic range is limited to 8-, 10-, 12- or 14-bit (data can be pure luminance for black and white sensor, RGB444, Bayer RGB, etc.). The pixel data is presented on `cam_d`, where one pixel is sampled for every `cam_pclk` rising edge (or falling edge, depending on the configuration of `cam_pclk` polarity). For more information, see [Section 1.4](#).

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (`cam_hs`) and vertical synchronization (`cam_vs`). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

**Note:** For correct operation, the clock `cam_pclk` must run during blanking periods (`cam_hs` and `cam_vs` inactive). `cam_pclk` must start before sending `cam_d` and start `cam_vs` and `cam_hs`.

[Figure 1-4](#) and [Figure 1-5](#) show the frame and data timing, respectively, based on synchronization signals in the parallel No BT configuration.

**Figure 1-4. Synchronization Signals and Frame Timing in SYNC mode**

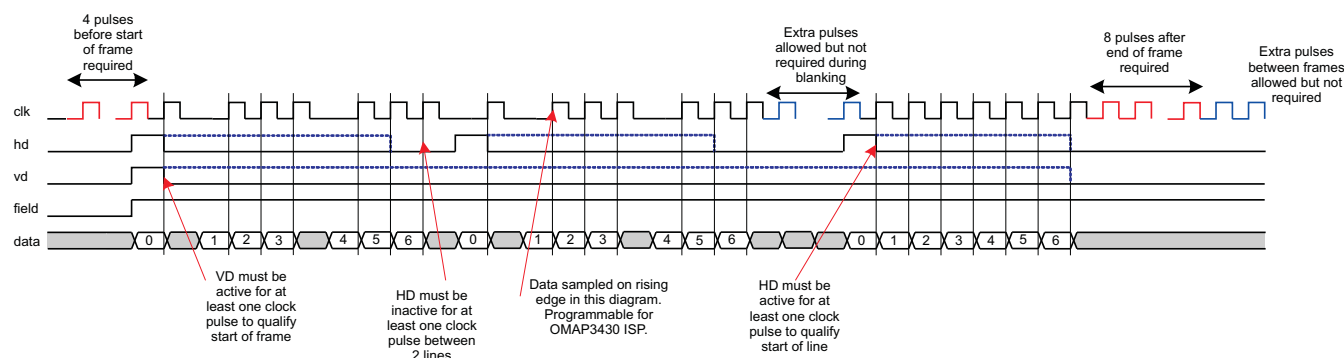

**Figure 1-5. Synchronization Signals and Data Timing in SYNC mode**

**Note:** The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least 4 clock pulses are required before sending active image data and synchronization information. 8 clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

Figure 1-6 shows the timing diagram of the SYNC move clock gating.

**Figure 1-6. SYNC Mode Clock Gating**

108-132

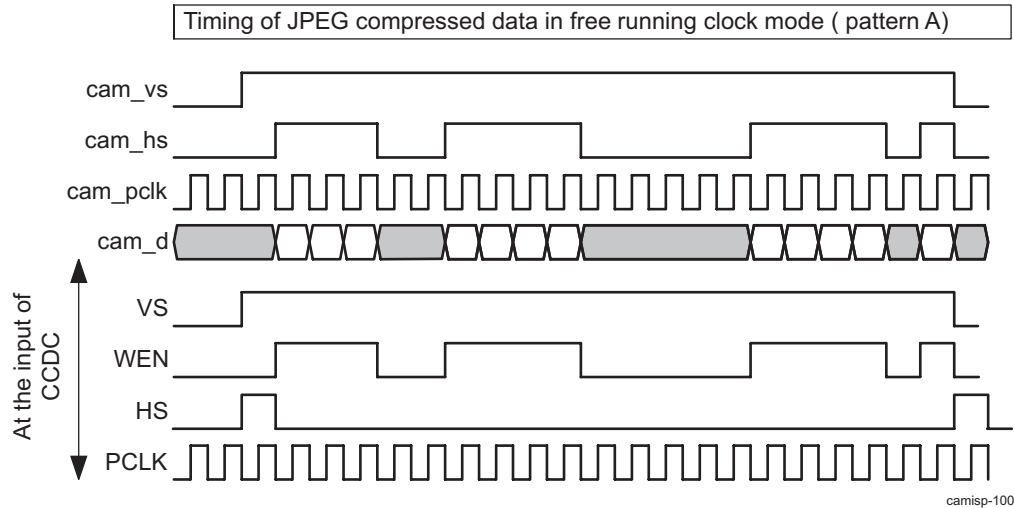

#### 1.2.4.2 Parallel Generic Configuration: JPEG Sensor Connection on the Parallel Interface

Some camera modules integrate an image-signal processor (ISP) and a JPEG encoder. The CCDC can interface with these camera modules and transfer the received JPEG stream to memory.

Only pattern A mode is supported. To use this mode, set the ISP\_CTRL [30] JPEG\_FLUSH bit.

Figure 1-7 shows timing diagrams for an A pattern.

**Figure 1-7. JPEG Stream Timing Diagrams**

**CAUTION**

The bridge cannot be used for JPEG sensor connections.

### 1.2.4.3 ITU-R BT.656 Protocol and Data Format (8, 10 Bits)

**CAUTION**

The ITU-R BT.656 mode cannot be used when the bridge is enabled.

The camera ISP interface supports data in ITU-R BT.656 format.

The ITU-R BT.656 standard specifies a method of transferring YUV422 data over an 8- or 10-bit video interface.

Figure 1-8 shows the data timing diagram with embedded synchronization signal.

**Figure 1-8. Data Timing With Embedded Synchronization Signals (8-Bit Case)**

In BT.656, the data words (8- or 10-bit) in which the eight most-significant bits (MSBs) are all set to 1, or all set to 0 are reserved. Only 254 of the possible 256 8-bit word values, and 1016 of the possible 1024 10-bit word values represent signal values.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved luminance and chroma samples and the following byte Y2n + 1 corresponds to the next luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cam\_hs and cam\_vs are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: **FF 00 00 XY**. The first 3 bytes are a fixed preamble (See the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 1-3 lists the video timing reference codes for SAV and EAV.

**Table 1-3. Video Timing Reference Codes for SAV and EAV**

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 1-4 contains a description of the F, V, and H signals.

**Table 1-4. F, V, H Signal Descriptions**

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the CCDC\_REC656IF [1] ECCFVH bit.

**Note:** The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

Table 1-5 lists the F, V, and H protection (error-correction) bits.

**Table 1-5. F, V, H Protection (Error-Correction) Bits**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0

**Table 1-5. F, V, H Protection (Error-Correction) Bits (continued)**

<b>F</b>	<b>V</b>	<b>H</b>	<b>P3</b>	<b>P2</b>	<b>P1</b>	<b>P0</b>
1	1	1	0	0	0	1

When operating in CCIR-656 mode, data is stored in SDRAM according to the format shown in [Table 1-6](#) when CCDC\_SYN\_MODE [11] PACK8 is enabled.

**Table 1-6. BT.656 Mode Data Format in SDRAM**

<b>8 bit x 4</b>	<b>Pixel3 (Y1/Cr0)</b>	<b>Pixel2 (Cr0/Y1)</b>	<b>Pixel1 (Y0/Cb0)</b>	<b>Pixel0 (Cb0/Y0)</b>
	Bit 31			Bit 0

**Note:** It is important to note that the CCDC outputs the XY code in the SAV and EAV into memory. To eliminate this, users must set the SPH register field to +1. In addition, the NPH register field must be set to accurately represent the number of active pixels.

## 1.3 Camera ISP Integration

Figure 1-9 shows the camera ISP integration.

**Figure 1-9. Camera ISP Integration**

camisp-021

### 1.3.1 Clocking, Reset, and Power-Management Scheme

#### 1.3.1.1 Clocks

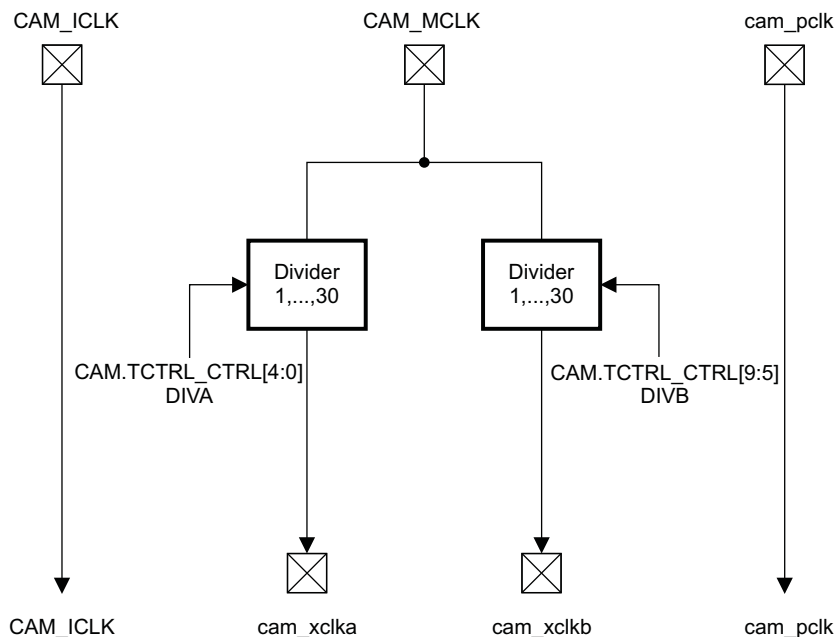

There are four clock domains in the camera ISP:

- Functional clock domain
- Interface clock domain
- Serial sensor clock domain
- Parallel sensor clock domain

### 1.3.1.1.1 Clock Tree

Figure 1-10 shows the clock tree for the camera ISP module.

Figure 1-10. Clock Tree

### 1.3.1.1.2 Clock Descriptions

Table 1-7 describes the camera ISP clocks.

Table 1-7. Clock Descriptions

Signal Name	I/O	Description
CAM_ICLK	Input	Interface clock (L4 interconnect clock domain) → Interface clock domain
CAM_MCLK <sup>(1)</sup>	Input	Internal clock from PRCM at 216 MHz. The CAM_MCLK is only used by the clock generator to generate cam_xclka and cam_xclkb
cam_xclka	Output	External clock for the image-sensor module. → For serial or parallel sensor
cam_xclkb	Output	External clock for the image-sensor module. → For serial or parallel sensor
cam_pclk	Input	Parallel mode: pixel clock for parallel input data. The data on the parallel interface are presented on cam_d, one pixel for every cam_pclk rising or falling edge. → Parallel sensor clock domain

<sup>(1)</sup> The CAM\_MCLK clock frequency can be ≤ 216 MHz.

### 1.3.1.1.3 Clock Configuration

- CAM\_FCLK control and settings

The CAM\_FCLK clock runs at the device L3 clock frequency.

The CAM\_FCLK source is the PRCM CAM\_L3\_ICLK output.

When the camera ISP no longer needs CAM\_FCLK, the software can disable it at PRCM level by setting the PRCM.CM\_ICLK\_CAM [0] EN\_CAM bit to 0x0. Note that the clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). For information, note that an automatic HW

handshake protocol takes place between the camera ISP and the PRCM to prevent CAM\_FCLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM\_AUTOIDLE\_CAM [0] AUTO\_CAM bit set to 1). This allows global management of the CAM\_FCLK clock along with the CAM power domain at PRCM level. For more information, see the *Power, Reset, and Clock Management* chapter.

- CAM\_ICLK control and settings

CAM\_ICLK is the interface clock. It runs at device L4 interconnect clock speed and triggers access to the camera ISP L4 interface. Its source is the PRCM CAM\_L4\_ICLK output.

When the camera ISP no longer needs CAM\_ICLK, the software can disable it at PRCM level by setting to 0x0 the PRCM.CM\_ICLK\_CAM [0] EN\_CAM bit. Note that the clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, It does not generate anymore traffic on the device interconnect and is internally idled). As information, note an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM\_ICLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM\_AUTOIDLE\_CAM [0] AUTO\_CAM bit set to 1). This allows global management of the CAM\_ICLK clock along with the CAM power domain at PRCM level. For more information, see the *Power, Reset, and Clock Management* chapter.

- CAM\_MCLK control and settings

The source for CAM\_MCLK is the PRCM CAM\_MCLK output. It is generated trough a peripheral DPLL and its frequency can be adjusted using the PRCM.CM\_CLKSEL\_CAM CLKSEL\_CAM bit field. When the module no longer needs it, it can be disabled at PRCM level by setting the PRCM.CM\_FCLKEN\_CAM EN\_CAM bit to 0x0. Note that the PRCM register bit setting has a direct effect on the clock; in other terms, there is no HW handshake protocol to ensure whether the clock can be cut regarding the camera ISP activity: as soon as the bit is set to 0x0, CAM\_MCLK is shut down.

- cam\_xclka and cam\_xclkb control and settings

cam\_xclka and cam\_xclkb are generated inside the camera ISP module from CAM\_MCLK clock input. [Table 1-8](#) and [Table 1-9](#) give the settings of the related bit fields.

**Table 1-8. cam\_xclka Configuration**

ref_clk	CAM.TCTRL_CTRL[4:0] DIVA field	cam_xclka
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2
	...	...
	0x1F	CAM_MCLK

**Table 1-9. cam\_xclkb Configuration**

ref_clk	CAM.TCTRL_CTRL[9:5] DIVB field	cam_xclkb
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2
	...	...
	0x1F	CAM_MCLK

### 1.3.1.2 Power Management

Power consumption can be reduced at two different levels:

- A local power-management optimization
- A system power management

### 1.3.1.2.1 Local Power Management

To optimize power consumption, a local autoidle feature is implemented on the CAM\_ICLK interface clock at camera ISP module level. By enabling this autoidle feature, CAM\_ICLK is automatically gated at the module boundary as soon as it is not required and restarted without any latency when needed again. This allows power saving when the module is not involved in any transfer from/to the device interconnect. This autoidle feature is enabled by setting:

- ISP\_SYSCONFIG [0] AUTO\_IDLE bit to 1
- MMU\_SYSCONFIG [0] AUTOIDLE bit to 1
- ISP\_CTRL [21] SBL\_AUTOIDLE bit to 1

The decision to gate the interconnect clock is based on interface activity, regardless of hardware handshake protocols.

After a reset, this mode is disabled, by default.

---

**Note:** It is recommended that this mode be enabled to reduce power consumption.

---

### 1.3.1.2.2 System Power Management

As part of the system power management scheme, the camera ISP module interacts with the PRCM through an automatic standby hardware protocol that allows dynamic power savings at CAMERA power domain level.

Being an initiator on the L3 interconnect, the camera ISP module alerts the PRCM as soon as it is ready to switch to a lower power state. Prior to any power state change to the CAMERA power domain, the PRCM first shuts off the camera clocks, depending on the camera ISP behavior and the clock settings at PRCM level. Namely, as soon as the camera ISP is ready to go to STANDBY, it asserts an automatic HW STANDBY request to the PRCM, which shuts down the clocks if they have been previously disabled by software and then potentially change the CAMERA power domain state. Refer to the *Power, Reset, and Clock Management* chapter for further details.

When it goes to standby, the camera ISP module alerts the PRCM differently, depending on the ISP\_SYSCONFIG [13:12] MIDDLE\_MODE bit field settings. The entry conditions for the camera ISP to go into standby mode are:

- The module has finished any current transaction and does not generate any more traffic on the interconnect.
- The module is idle (on-going transactions are finished).

The MIDDLE\_MODE bit field allows the following settings for the camera ISP module:

- Force standby  
The camera ISP is set to force standby when MIDDLE\_MODE is set to 0x0. In this mode, the camera ISP module asserts its HW standby request to the PRCM as soon as it is disabled. Namely, the camera ISP is disabled when the following bit fields are set to 0x0:
  - ISP\_CTRL [13] RSZ\_CLK\_EN
  - ISP\_CTRL [12] PRV\_CLK\_EN
  - ISP\_CTRL [11] HIST\_CLK\_EN
  - ISP\_CTRL [10] H3A\_CLK\_EN
  - ISP\_CTRL [8] CCDC\_CLK\_EN
- No standby  
The camera ISP is set to no standby when MIDDLE\_MODE is set to 0x1. In this mode, the camera ISP module never asserts its standby request to the PRCM. Note that this also prevents the CAMERA power domain from going to a lower power state. Refer to the *Power, Reset, and Clock Management* chapter for further details.
- Smart standby  
The camera ISP module is set to smart standby when MIDDLE\_MODE is set to 0x2. In this mode, the camera ISP module asserts its HW standby request to the PRCM according with its internal activity (namely, when there is no more activity on the camera ISP master interface, that is, when there is no

more data in the central resource buffer).

Note that a standby request asserted to the PRCM does not necessarily lead to CAM\_FCLK and CAM\_ICLK being cut. Indeed, the PRCM must also be set correctly for that purpose.

The clocks are cut, allowing a CAMERA power state change if:

- PRCM.CM\_ICLKEN\_CAM[0] EN\_CAM = 0 and PRCM.CM\_FCLKEN\_CAM[0] EN\_CAM = 0
- PRCM.CM\_FCLKEN\_CAM[0] EN\_CAM = 0, (PRCM.CM\_ICLKEN\_CAM[0] EN\_CAM = 1, PRCM.CM\_AUTOIDLE\_CAM[0] = 1, and a domain transition is required at PRCM level).

Refer to the *Power, Reset, and Clock Management* chapter for further details.

### 1.3.1.3 Power Domain

The camera ISP belongs to the CAMERA power domain. For more information about the CAMERA power domain, see the *Power, Reset, and Clock Management* chapter.

### 1.3.1.4 Resets

#### 1.3.1.4.1 Hardware Reset

Global reset of the camera ISP module is accomplished by activation of the CAM\_RST signal in the CAMERA domain (for more information, see the *Power, Reset, and Clock Management* chapter).

#### 1.3.1.4.2 Software Reset

A global software reset can be accomplished by setting the camera ISP ISP\_SYSCONFIG [1] SOFT\_RESET bit to 1. Setting this bit enables active software reset functionality equivalent to hardware reset for the entire module.

## 1.3.2 Hardware Requests

### 1.3.2.1 Interrupt Requests

Figure 1-11 shows the interrupt generation tree of the camera subsystem.

### Figure 1-11. Interrupt Generation Tree

The camera ISP can generate two interrupts:

- CAM\_IRQ0 is an interrupt to the MPU subsystem interrupt controller. It is mapped on M\_IRQ\_24.
- CAM\_IRQ1 is an interrupt to the IVA2.2 subsystem interrupt controller. It is mapped on IVA2\_IRQ[11].

Table 1-10 summarizes events that cause interrupts.

### Table 1-10. Camera ISP Interrupts

Event	Mask	Description
ISP_IRQ0STATUS [31] HS_VS_IRQ	ISP_IRQ0ENABLE [31] HS_VS_IRQ	HS or VS synchronization event: triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen with the ISP_CTRL [15:14] SYNC_DETECT bit field.
ISP_IRQ0STATUS [30] SEC_ERR_IRQ	ISP_IRQ0ENABLE [30] SEC_ERR_IRQ	Security error event: triggered when a privilege violation error occurs.
ISP_IRQ0STATUS [29] OCP_ERR_IRQ	ISP_IRQ0ENABLE [29] OCP_ERR_IRQ	ISP OCP error: triggered when an OCP error occurs: SResp = ERR. The cause may be a security violation.
ISP_IRQ0STATUS [28] MMU_ERR_IRQ	ISP_IRQ0ENABLE [28] MMU_ERR_IRQ	MMU error

**Table 1-10. Camera ISP Interrupts (continued)**

Event	Mask	Description
ISP_IRQ0STATUS [25] OVF_IRQ	ISP_IRQ0ENABLE [25] OVF_IRQ	Central-resource SBL overflow: triggered when one of the buffers in the central-resource SBL overflows.
ISP_IRQ0STATUS [24] RSZ_DONE_IRQ	ISP_IRQ0ENABLE [24] RSZ_DONE_IRQ	RESIZER module - resizer processing-done event: Triggered at the end of the frame when processing is complete for the current frame. It applies to one-shot and continuous modes.
ISP_IRQ0STATUS [21] CBUFF_IRQ	ISP_IRQ0ENABLE [24] CBUFF_IRQ	CBUFF module event. See CBUFF_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [20] PRV_DONE_IRQ	ISP_IRQ0ENABLE [20] PRV_DONE_IRQ	PREVIEW module - processing-done event: triggered at the end of the frame when processing is complete for the current frame.
ISP_IRQ0STATUS [19] CCDC_LSC_PREFETCH_ERROR	ISP_IRQ0ENABLE [19] PRV_DONE_IRQ	CCDC module - The prefetch error indicates when the gain table was read too slowly from memory. When this event is pending, the module goes into transparent mode (output = input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it
ISP_IRQ0STATUS [18] CCDC_LSC_PREFETCH_COMPLETED	ISP_IRQ0ENABLE [18] CCDC_LSC_PREFETCH_COMPLETED	CCDC module - Indicates the current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks.
ISP_IRQ0STATUS [17] CCDC_LSC_DONE	ISP_IRQ0ENABLE [17] CCDC_LSC_DONE	CCDC module - The event is triggered when the internal state of LSC toggles from BUSY to IDLE. This happens when the LSC module has completed processing the current frame.
ISP_IRQ0STATUS [16] HIST_DONE_IRQ	ISP_IRQ0ENABLE [16] HIST_DONE_IRQ	HIST module - processing-done event: triggered at the end of the frame when processing is complete for the current frame.
ISP_IRQ0STATUS [13] H3A_AWB_DONE_IRQ	ISP_IRQ0ENABLE [13] H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event: Triggered at the end of the frame when processing is complete for the current frame.
ISP_IRQ0STATUS [12] H3A_AF_DONE_IRQ	ISP_IRQ0ENABLE [12] H3A_AF_DONE_IRQ	H3A module - autofocus processing-done event: triggered at the end of the frame when processing is complete for the current frame.
ISP_IRQ0STATUS [11] CCDC_ERR_IRQ	ISP_IRQ0ENABLE [11] CCDC_ERR_IRQ	CCDC module - Faulty-pixel correction error: Faulty-pixel correction memory underflow. Triggered to signal an error in the faulty-pixel correction logic. The hardware did not have time to read the faulty-pixel LUT from external memory in time.
ISP_IRQ0STATUS [10] CCDC_VD2_IRQ	ISP_IRQ0ENABLE [10] CCDC_VD2_IRQ	CCDC module - Programmable event 2: triggered by the falling edge on the cam_wen signal. This event is not programmable.
ISP_IRQ0STATUS [9] CCDC_VD1_IRQ	ISP_IRQ0ENABLE [9] CCDC_VD1_IRQ	CCDC module - Programmable event 1: triggered after a programmable number of horizontal lines is received after a VS pulse.
ISP_IRQ0STATUS [8] CCDC_VD0_IRQ	ISP_IRQ0ENABLE [8] CCDC_VD0_IRQ	CCDC module - Programmable event 0: triggered after a programmable number of horizontal lines is received after a VS pulse.

**Note:** n is equal to 0 or 1.

l is equal to 01 or 23.

Table 1-11 summarizes the CBUFF interrupts.

**Table 1-11. CBUFF Interrupt Details**

Event	Mask	Description
CBUFF_IRQSTATUS [5] IRQ_CBUFF1_OVR	CBUFF_IRQENABLE [5] IRQ_CBUFF1_OVR	Buffer overflow event: The generation of this event depends on the CBUFFx_CTRL.ALLOW_NW_EQ_CR flag and the circular buffer mode (read or write). This event indicates a bandwidth mismatch between data producer and data consumer. When it occurs, CBUFFx does NOT go into error state. However, the data in the physical buffer is very likely to be corrupted.
CBUFF_IRQSTATUS [4] IRQ_CBUFF1_INVALID	CBUFF_IRQENABLE [4] IRQ_CBUFF1_INVALID	Invalid access: <ul style="list-style-type: none"> <li>ISP writes the virtual space of CBUFFx in read mode.</li> <li>ISP reads the virtual space of CBUFFx in write mode.</li> <li>HW writes the virtual space of circular buffer x outside the CW or NW window in write mode.</li> <li>HW reads the virtual space of circular buffer x outside the CW or NW window in read mode.</li> <li>NW full</li> <li>CPU write the DONE bit when physical buffers are not ready for the CPU.</li> </ul> <p>This event indicates a wrong configuration of the circular buffer, the camera ISP, or bogus software. When it occurs, CBUFFx goes into an error state. In this state all accesses to the virtual space of CBUFFx are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory.</p> <p>The error state can be left by disabling the CBUFFx and reenabling it. Before doing so, the SW must ensure that there are no more outstanding requests to the virtual space of CBUFFx.</p>
CBUFF_IRQSTATUS [3] IRQ_CBUFF1_READY	CBUFF_IRQENABLE [3] IRQ_CBUFF1_READY	The CPUW1 physical buffer is ready to be accessed by the CPU.
CBUFF_IRQSTATUS [2] IRQ_CBUFF0_OVR	CBUFF_IRQENABLE [2] IRQ_CBUFF0_OVR	Buffer overflow event. See description of IRQ_CBUFF1_OVR event.
CBUFF_IRQSTATUS [1] IRQ_CBUFF0_INVALID	CBUFF_IRQENABLE [1] IRQ_CBUFF0_INVALID	Invalid access. See description of IRQ_CBUFF1_INVALID event.
CBUFF_IRQSTATUS [0] IRQ_CBUFF0_READY	CBUFF_IRQENABLE [0] IRQ_CBUFF0_READY	The CPUW1 physical buffer is ready to be accessed by the CPU

## 1.4 Camera ISP Functional Description

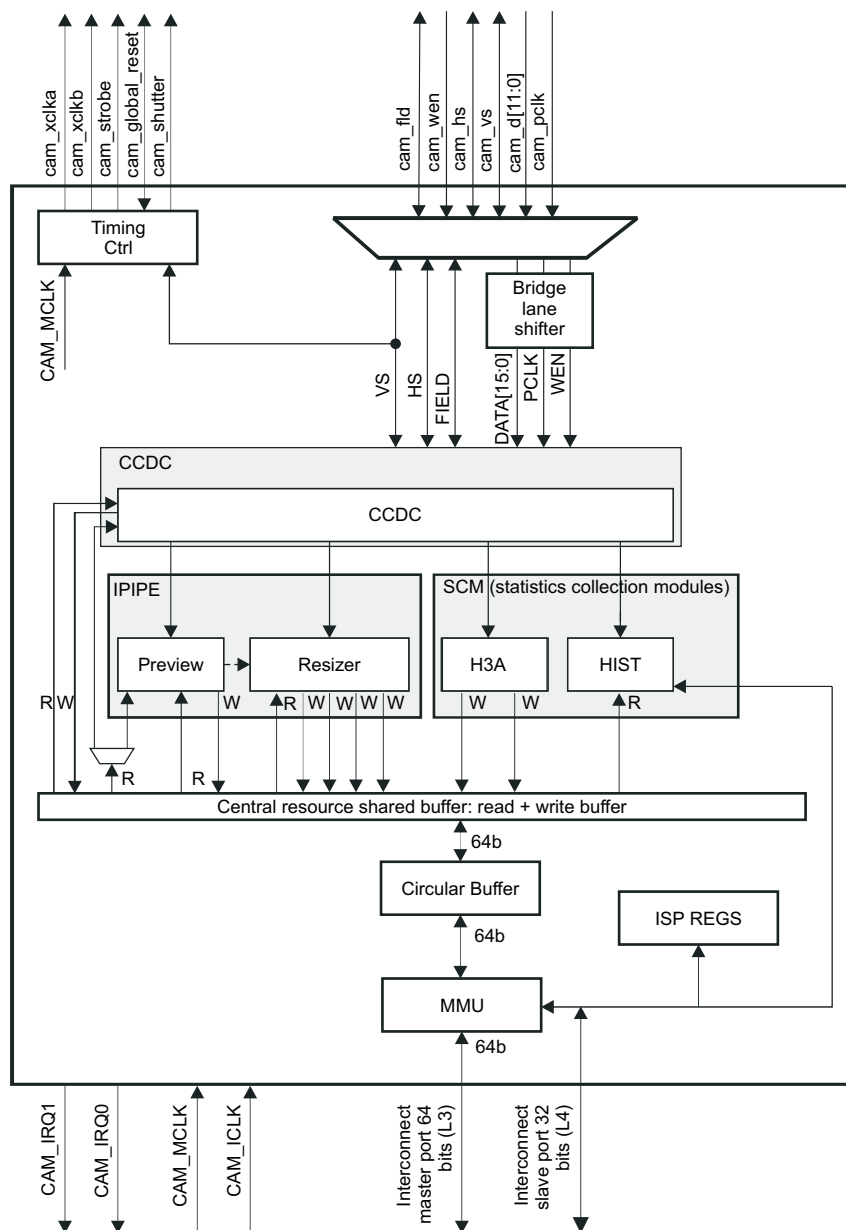

### 1.4.1 Block Diagram

Figure 1-12 is the camera ISP top-level block diagram. The camera ISP supports two simultaneous pixel flows, but only one of them can use the video-processing hardware at a time:

The camera ISP master port is connected to the L3 interconnect, and the slave port is connected to the L4 interconnect (from the camera ISP point of view, commands are output from the camera ISP to the L3 and data are input/output. From the camera ISP point of view, commands are input from the L4 to the camera ISP and data are input/output).

Figure 1-12 shows the camera ISP block diagram.

Figure 1-12. Camera ISP Block Diagram

camisp-025

The camera ISP module comprises several blocks:

- Timing control: Includes a timing generator and a control-signal generator:
  - The timing generator allows the generation of two clocks that can be used by the external image sensors.

- The control-signal generator allows the generation of signals for strobe flash, mechanical shutter, and global reset.
- Bridge-lane shifter:
  - The data-lane shifter gives flexibility to the parallel camera connection and permits dynamic reduction of pixel data.
  - The bridge allows higher transfer rates when data is captured from the parallel interface and sent to memory.
- CCDC: This module provides the camera ISP with a powerful and flexible front end interface. It directly affects the input image data:
  - The CCDC provides an interface to image sensors and digital video sources and processes image data.
- IPIPE: Comprises preview and resizer modules:
  - The preview module is a parameterized hardwired image-processing block whose image-processing functions can be customized for each sensor type to realize good image quality and video frame rates for digital still camera preview displays and video-recording modes.
  - The resizer module provides a means of sizing the input image data to the desired display or video-encoding resolution. Zoom is limited to 4x in both vertical and horizontal directions for each pass. After one (on-the-fly) upscaling pass, the image can be sent to memory and then resent through the resizer.
- Statistics-collection modules (SCM): H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems:
  - The hardware 3A module supports the control loops for AF, AWB, and AE by collecting metrics about RAW image data from the CCDC.
  - The histogram module bins input color pixels, depending on the amplitude, and provide statistics required to implement various 3A (AE/AF/AWB) algorithms and tune the final image/video output. The histogram module can operate on RAW image data from CCDC or memory.
- Central-resource shared buffer logic (CRSBL): Buffers and schedules memory accesses requested by the camera modules
- Circular buffer: Avoids storage of full image frames in the memory when the data must be post and/or preprocessed by software.
- MMU: Performs virtual-to-physical address translation between its interconnect slave and interconnect master access ports

#### 1.4.1.1 Possible Data Paths inside the Camera ISP

Data paths inside the camera ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG,...).

[Table 1-12](#) lists the modules used for the different data types. The formats described in the columns are the formats at the inputs of the CCDC (after the bridge-lane shifter). It is the internal parallel format.

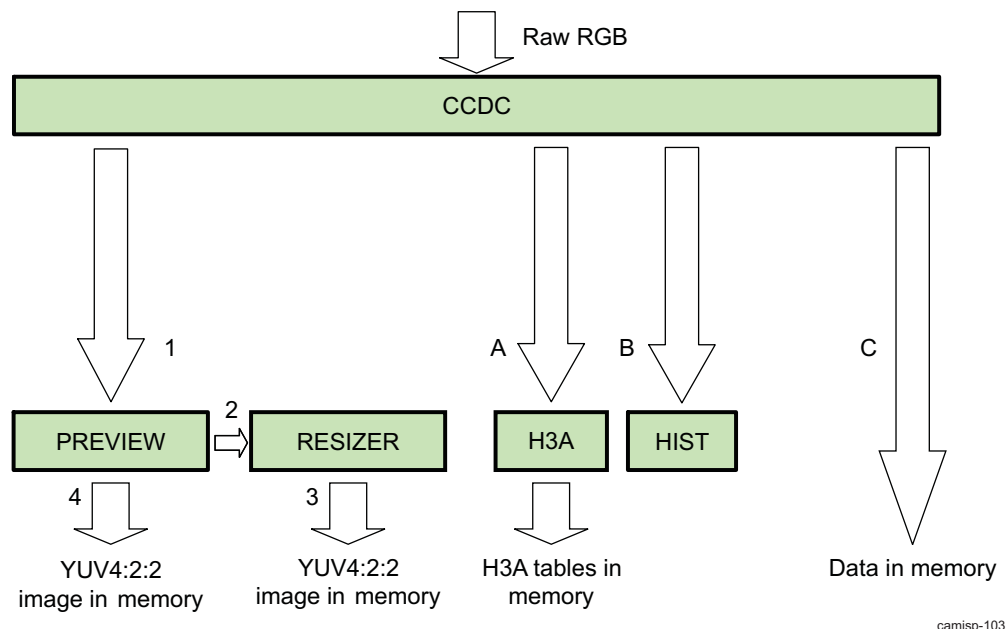

**Table 1-12. Allowed Data Flows for Hardware at the Input of the CCDC Module**

Module	6/7 Bits RAW Format	8/10 Bits RAW Format	11/12/14 Bits RAW Format	YUV4:2:2 Format	Other Formats (JPEG,RGB4:4:4,...)
CCDC	+	+	+	+	+ All formats not treated by hardware
Preview	+	+			
Resizer	+	+		+	
H3A	+ Except AF	+ Except AF for RAW8			
Histogram	+	+			

### 1.4.1.1.1 RGB RAW Data

Figure 1-13 shows the data path of images in RAW format.

**Figure 1-13. Camera ISP/Data Path/RAW RGB Images**

RAW data are processed through the CCDC module and are directly pipelined to the preview engine. Another way is to output directly from the CCDC to memory. In the preview block; the format is converted from RAW data to YUV4:2:2 (1). The data can be output to memory (4) or pipelined to the resizer (2). The rescaled YUV4:2:2 image is finally stored in memory (3).

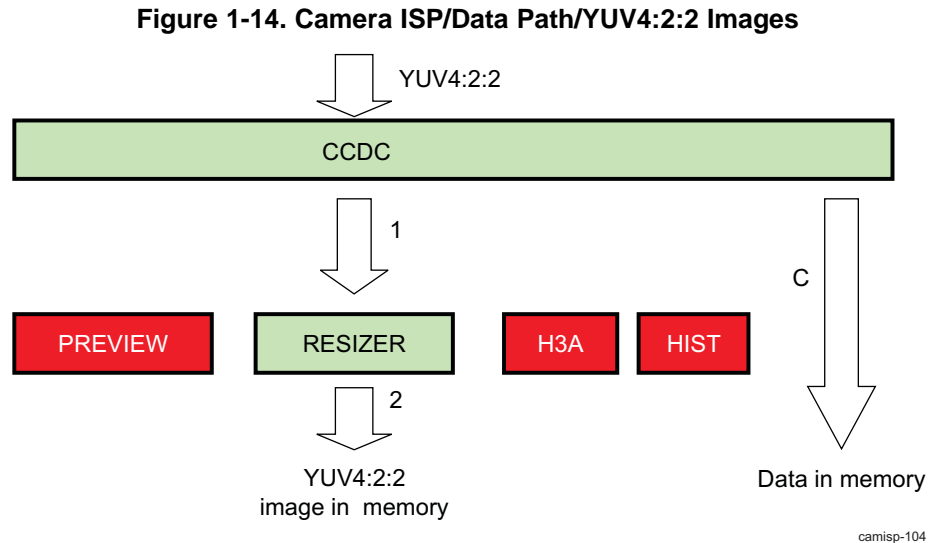

In parallel, processed data in the CCDC are used by the H3A module (A), which writes tables of statistics in memory, and by the HIST module (B). The results of the HIST modules are stored in status registers in the HIST module.

#### Notes:

- This data path is correct for RAW10 data.
- The data path for RAW8 data is similar to that for RAW10, except that the autofocus module in the H3A does not support RAW8.
- RAW11 data must be sent directly to memory).
- RAW12 data must be sent to memory) or pixel dynamic must be reduced RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.
- RAW14 data must be sent to memory) or pixel dynamic must be reduced to RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.

#### 1.4.1.1.2 YUV4:2:2 Data

Figure 1-14 shows the data path of images in YUV4:2:2 format.

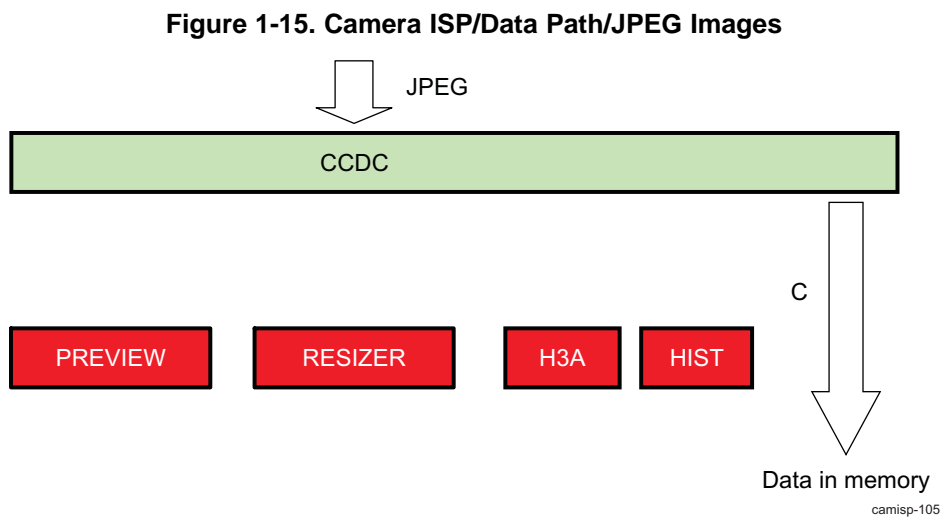

When the sensor-output format is YUV4:2:2, the CCDC block is directly pipelined to the resizer (1) or output directly to the memory (2). The rescaled YUV4:2:2 images are finally stored in memory (2).

The modules in red in Figure 1-14 are not used when the format is YUV4:2:2.

#### 1.4.1.1.3 JPEG Data

Figure 1-15 shows the data path of images in JPEG format.

When the sensor output format is JPEG, the CCDC block is directly output to the memory (2).

The modules in red in Figure 1-15 are not used when the format is JPEG.

## 1.4.2 Timing Control

### 1.4.2.1 Timing-Control Features

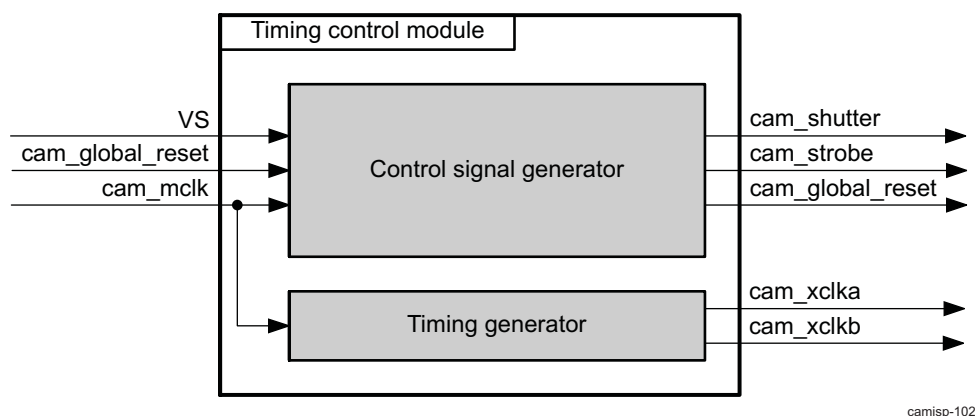

The timing-control module provides two clocks (cam\_xclka and cam\_xclkb) that can be used by external camera modules. It also generates the control signals (cam\_strobe and cam\_shutter) for the flash prestrobe, flash strobe, and mechanical shutters.

The timing-control module includes a timing generator and a control-signal generator.

### 1.4.2.2 Timing Control

Figure 1-16 shows a block diagram of the timing-control module.

**Figure 1-16. Timing-Control Module**

camisp-102

#### 1.4.2.2.1 Timing Generator

The timing generator generates the cam\_xclka and cam\_xclkb clocks based on the cam\_mclk, which is equal to 216 MHz. The CAM\_MCLK clock frequency can be  $\leq 216$  MHz. The cam\_mclk is used only by the clock generator; the cam\_xclka and cam\_xclkb clocks are not used internally by the camera ISP. The clock divider is programmable.

The possible frequencies of cam\_xclka and cam\_xclkb and their respective configurations are described in [Section 1.3.1.1.3, Clock Configuration](#).

[Table 1-13](#) summarizes the possible frequencies as a function of the divisor values.

#### 1.4.2.2.2 Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam\_strobe and cam\_shutter.

The control-signal generator gathers precise timings for the cam\_strobe and cam\_shutter signals, to assert and deassert the signals at known times. The timing-control-signal generator can be synchronized either on the vertical synchronization signal coming from the PARALLEL interface (cam\_vs), or on an externally generated cam\_global\_reset signal.

A multiplexer controls the PARALLEL interface drives control-signal generation. This multiplexer can also select the externally-generated cam\_global\_reset signal as the trigger event. The TCTRL\_CTRL [31] GRESETDIR register defines the direction of the cam\_global\_reset signal.

- The external generated cam\_global\_reset is used as a trigger when TCTRL\_CTRL [31] GRESETDIR = 0 and TCTRL\_CTRL[27:28] INSEL = 3.
- The internally generated cam\_global\_reset is used as a trigger when TCTRL\_CTRL [31] GRESETDIR = 1 and TCTRL\_CTRL[27:28] INSEL = 3.
- If the PARALLEL interface is selected, control-signal generation works for both ITU and SYNC modes

and on both output ports: video port and shared-buffer-logic (SBL) port.

The cam\_global\_reset signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on the internally generated cam\_global\_reset signal. The multiplexer controls whether control-signal generation must be triggered by the internal or external cam\_global\_reset signal.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the cam\_mclk clock. The clock divider is programmable. [Table 1-13](#) summarizes the possible frequencies as a function of the divisor values.

**Table 1-13. Control-Signal Generator: CNTCLK Frequencies**

Divisor Value TCTRL_CTRL [18:10] DIVC	CNTCLK Clock
0 (default)	Clock gated. No clock.
1	216 MHz, free-running.
2	108 MHz
3	72 MHz
4	54 MHz
...	...
510	0.424 MHz
511	0.423 MHz

There are three counters per control signal, for a total of nine counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received, based on the EOF events from the CCDC.
  - A new frame is detected in the CCDC module by using the falling edge of the vertical synchronization signal at the input of the CCDC module.

---

**Note:** The rising edge of the vertical synchronization signal and the vertical synchronization polarity settings inside the CCDC cannot be used. The modules have no effect on this detection.

---

- The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass them.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the control-signal assertion length. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

The polarity of the following signals can be individually selected:

- TCTRL\_CTRL [26] STRBPSTRBPOL for the prestrobe and strobe signals
- TCTRL\_CTRL [24] SHUTPOL for the shutter signal
- TCTRL\_CTRL [30] GRESETPOL for the cam\_global\_reset signal

The software can trigger the generation of the cam\_global\_reset signal to the camera module. The signal-activation length is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled (TCTRL\_CTRL [29] GRESETEN bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of the cam\_global\_reset signal can be selected (TCTRL\_CTRL [30] GRESETPOL bit).

### 1.4.3 Bridge-Lane Shifter

The bridge-lane shifter module contains a data-lane shifter and an optional bridge:

- The data-lane shifter routes data sent to physical pins to the proper inputs of the CCDC module. It is controlled by the ISP\_CTRL [7:6] SHIFT register. [Table 1-14](#) describes the different configurations.

**Table 1-14. Data-Lane Shifter**

Sensor	Connected to	Data Lane shifter 0	Data Lane shifter 1	Data Lane shifter 2	Data Lane shifter 3	Note
8 bits	[7:0]	8 bits	6 bits	4 bits	2 bits	
	[9:2]	10 bits	8 bits	6 bits	4 bits	
	[11:4]	12 bits	10 bits	8 bits	6 bits	
10 bits	[9:0]	10 bits	8 bits	6 bits	4 bits	
	[11:2]	12 bits	10 bits	8 bits	6 bits	
12 bits	[11:0]	12 bits	10 bits	8 bits	6 bits	

Blue shading means that the data is too wide for the image pipeline: use IVA2.2.

Green shading means that precision is increased for intermediate results.

Orange shading means that precision is reduced.

Unshaded cells imply normal precision.

- An optional bridge allows the packing of bytes into 16-bit words. When it is used, the maximum data rate allowed is increased. The placement of 8-bit data inside 16-bit words is configurable through the ISP\_CTRL [3:2] PAR\_BRIDGE register. This mode can be useful to transfer an YCbCr data stream or compressed stream to memory at very high speed:
  - A minimum line-blanking period of 2 pixels must be obeyed when the bridge is enabled.
  - Some CCDC modules cannot work with the bridge. For details, see [Table 1-15](#).

### 1.4.4 CCDC

#### 1.4.4.1 CCDC Features

The CCDC is responsible for accepting RAW (unprocessed) image/video data from a sensor. It can also accept YUV video data in numerous formats. For RAW inputs, the CCDC output requires additional image processing to transform the input image to a final processed image. This processing can be performed either on-the-fly in the preview engine, or in software on the IVA2.2 subsystem. In parallel, RAW data input to the CCDC can be used for computing statistics (H3A, histogram) to eventually control image/video tuning parameters. The CCDC module supports the following features:

- Image sensors:** Supports most image sensors (resolutions up to 4096 x 4096).
- CCDC interface:** The camera ISP module interface comes either from the external parallel interface. It is a 16-bit interface. To raise this maximum 16-bit interface, the bridge data-lane shifter before the CCDC module allows the packing of 8-bit data into 16 bits (not supported with ITU mode):
  - Data up to 8-bit at 130 MHz can be transferred to memory.
  - Data up to 10-bit at 75 MHz can be processed by the image pipeline or transferred to memory.
  - Data up to 12-bit at 75 MHz can be transferred to memory or internally converted into 10-bit data to be processed by the image pipeline.
  - Supports two synchronization modes:
    - SYNC mode:** In this mode, the cam\_hs and cam\_vs signals use dedicated wires. Synchronization signals are provided by either the sensor or the camera ISP. This mode works with 8-, 10-, 11-, and 12-bit data. It supports both progressive and interlaced image-sensor modules.
    - ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. Horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds SAV and EAV synchronization code. This mode works in 8- and 10-bit configurations. It supports only progressive image-sensor modules.

- **RAW data processing:** Output data can go directly to memory for software processing, or to the PREVIEW module for further processing. The operations include:
  - Optical clamp
  - Black-level compensation
  - Faulty-pixel correction
  - 2D map based lens-shading compensation
  - Data formatter
  - Output formatter
- **YUV data processing:** The output data can go directly to memory for software processing or to the resizer module for further processing. The operations include:
  - DC subtract
  - Culling
  - Output formatter
- **Memory ports:** The CCDC module can access memory as a master through the CRSBL, so it does not require the assistance of the system DMA.

#### 1.4.4.2 CCDC Block Diagram

Figure 1-17 shows the top-level block diagram of the CCDC module.

Figure 1-17. CCDC Block Diagram

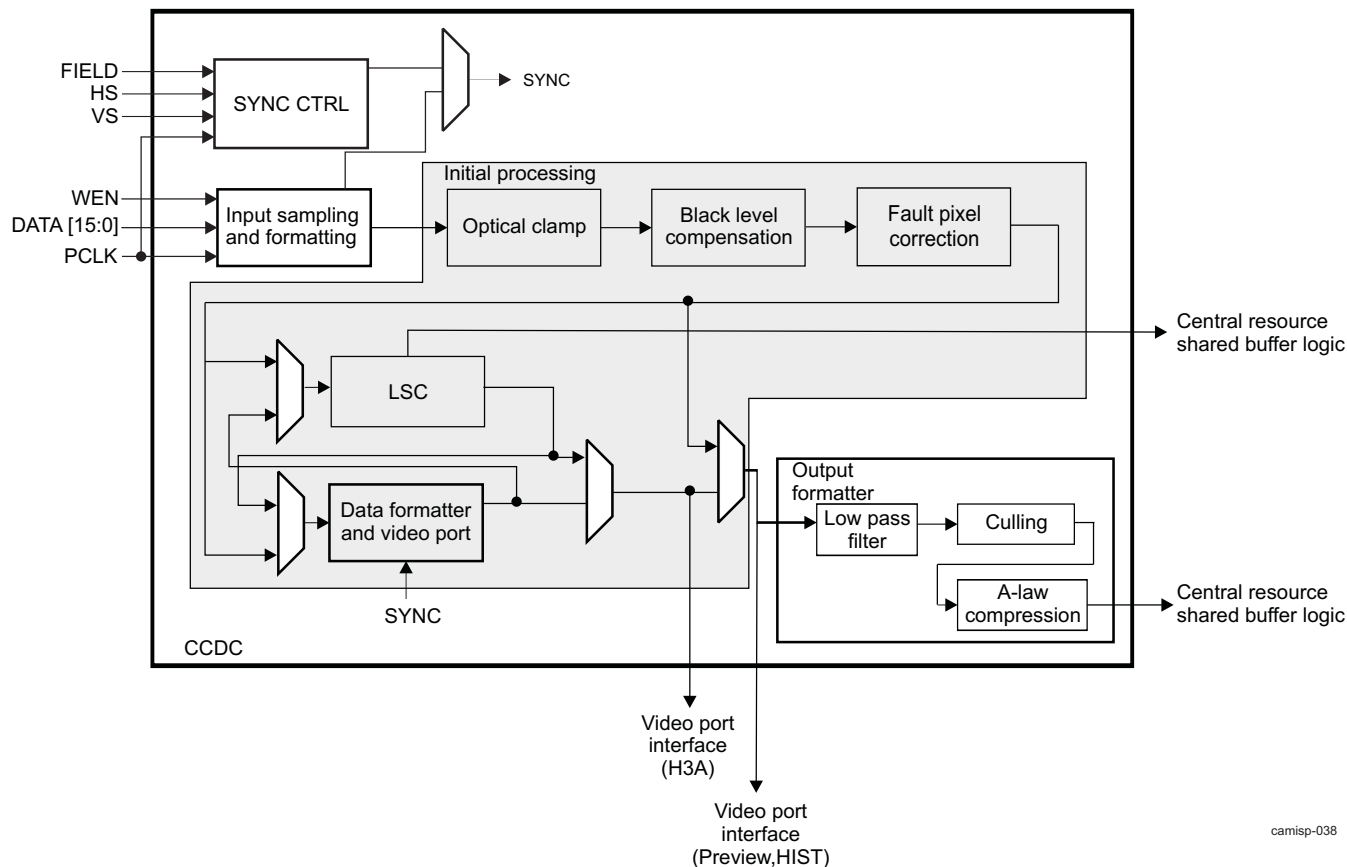

Table 1-15 summarizes allowed data flows through the CCDC.

camisp-038

**Table 1-15. Allowed Data Flows Through the CCDC**

Module		6/7 Bits RAW Format, SYNC Mode	8/10 Bits RAW Format, SYNC Mode	11/12 Bits RAW Format, SYNC Mode	8/10 Bits YUV4:2:2 Format, BT656 Mode	8/10 Bits YUV4:2:2 Format, SYNC Mode <75 MHz	8/10 Bits YUV4:2:2 Format, SYNC Mode <130 MHz	Other Formats (JPEG...), SYNC Mode
Bridge data-lane shifter	Bridge						+	
CCDC- SYNC CTRL	SYNC CTRL	+	+	+		+	+	+
CCDC-Input sampling and formatting	BT656 decoder				+			
CCDC-Initial processing	DC subtract	+	+	+	+	+	+	
	Optical black clamp	+	+	+				
	Black-level comp	+	+	+				
	Faulty-pixel correction	+	+	+				
CCDC-Data formatter	Data formatter	+	+					
	Shading compensator		+					
	Preview, H3A, HIST data path	+	+					
CCDC- Output formatter	Pixel selection	+	+	+	+	+	+	
	Low-pass filter	+	+	+				
	Culling	+	+	+	+	+	+	
	A-Law	+	+	+				
	Resizer data path				+	+	+	
	Memory data path	+	+	+	+	+	+	+

The data flow through the module differs, depending on whether the input is RAW data or YUV data. It also depends on the application scenario.

For RAW8/10 data (CCDC\_SYN\_MODE [13:12] INPMODE = 0 && CCDC\_REC656IF [0] REC656ON = 0), the following functions apply:

- Video-preview and video-capture data flows can pass through the optical-clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Output is transmitted to the HIST H3Amodules for further processing.
- JPEG still-image-capture data flow passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Then the data flow is sent to memory through the SBL, Circular buffer, and MMU to be read by the external JPEG CODEC.
- RAW still-image-capture data flow typically passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator and output-formatter submodules.

For YUV data (CCDC\_SYN\_MODE [13:12] INPMODE = 1 or 2 && CCDC\_REC656IF [0] REC656ON = 1), the following functions apply:

- Data can be written to memory directly through the central-resource SBL module or sent to the resizer module for upscaling or downscaling.

### 1.4.4.3 CCDC Functional Operations

#### 1.4.4.3.1 SYNC CTRL Module

The SYNC CTRL module receives the pixel-clock signal from the image sensor (PCLK). The module can be slave or master of the horizontal and vertical synchronization signals (HS and VS) and of the field-identification signal (FIELD).

The HS, VS, and FLD signals can be set as inputs or outputs. The polarity of the HS, VS, and FLD signals can be set as positive or negative. If the HS, VS, and FLD signals are output, the signal length can be set.

#### 1.4.4.3.2 Input Sampling and Formatting

CCDC input sampling and formatting are shown in . In this block diagram, the lower data path (A2 output) is the RAW data path; the middle data path (A1 output) is the YUV data path.

- Data is latched by the pixel clock.
- Pixel-clock polarity can be either rising- or falling-edge. This is set through ISP\_CTRL [4] PAR\_CLK\_POL.
- Data can be interpreted as normal or inverted (CCDC\_SYN\_MODE[6] DATAPOL).
- For RAW data:
  - Data is clipped to the number of LSBs specified in the CCDC\_SYN\_MODE [10:8] DATSIZ field. This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment if data is written to memory.
- For YUV data (BT656 or SYNC mode):
  - The MSB of the chroma signal can also be inverted (CCDC\_CFG [13] MSBINVI). It adds 128 to chrominance signals, to be compatible with several sensors.
- BT656 decoder: Separates data and synchronization signals. This module outputs HS, VS, and FIELD signals.

#### 1.4.4.3.3 CCDC Initial Processing

##### Optical Clamp

The optical black clamping function provides a means of averaging the optically black pixels and subtracting that value from each input pixel as a first step. The goal is to remove an offset caused by the sensor technology.

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start (CCDC\_CLAMP [24:10] OBST) of each line (CCDC\_CLAMP [30:28] OBSLEN) and for the number of indicated lines (CCDC\_CLAMP [27:25] OBSLN), plus an optional gain adjustment (CCDC\_CLAMP [4:0] OBGAIN), and subtracting this value from the image data at the succeeding line. Users can control the position of the black pixels, the number of pixels (1, 2, 4, 8, or 16) in each line averaged, and the averaged number of lines (1, 2, 4, 8, or 16).

Alternately, users can disable black clamp averaging (CCDC\_CLAMP [31] CLAMPEN) and select a constant black value for subtraction (CCDC\_DCSUB [13:0] DCSUB), instead of using the calculated average value.

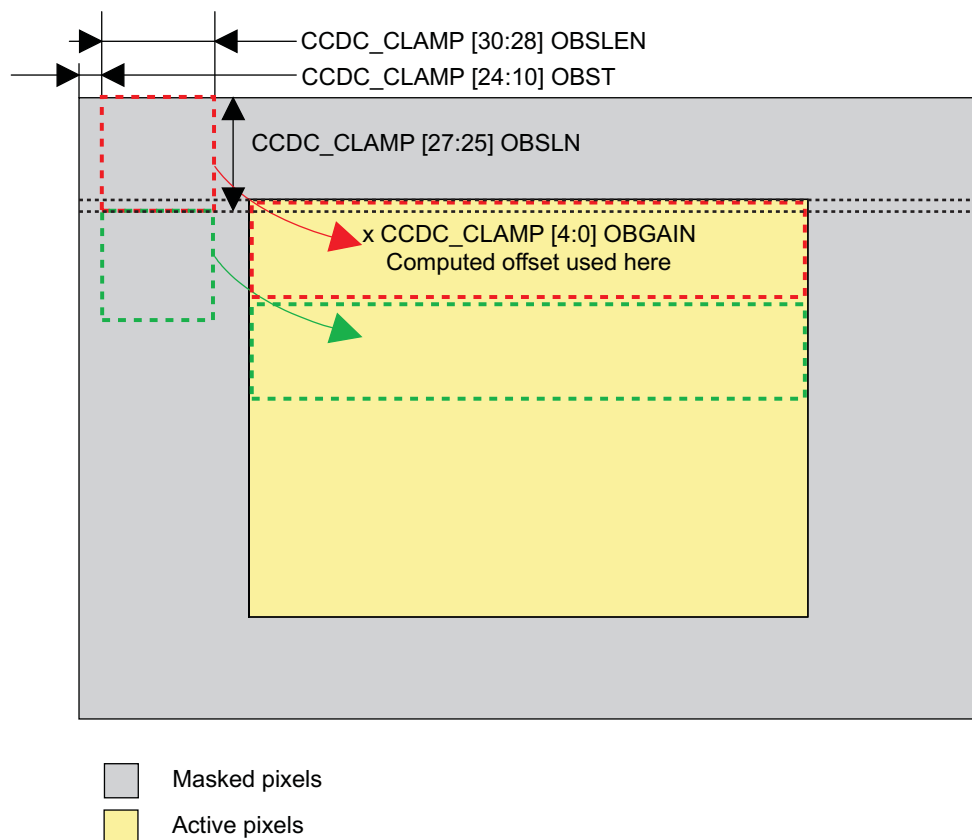

---

**Note:** For YUV data, this operation subtracts a fixed value (CCDC\_DCSUB [13:0] DCSUB) from the luminance sample. To disable this operation, set the subtraction value to zero.

This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes (CCDC\_SYN\_MODE [13:12] INPMOD == 2 || CCDC\_REC656IF [0] REC656ON == 1).

---

Figure 1-18 shows an optical clamp representation.

**Figure 1-18. Optical Clamp Representation**

camisp-106

## Black-Level Compensation

After the optical clamp, black-level compensation is applied to the data. In this operation, a fixed value, depending on the color (R/Ye, Gr/Cy, Gb/G, and B/Mg), can be subtracted from the data. The offset (CCDC\_BLKCOMP register, fields R\_YE, GR\_CY, GB\_G, B\_MG) applied to each data sample is selected according to the pixel position (0/1/2/3) and the color (0/1/2/3) specified for each pixel position (CCDC\_COLPTN). The color pattern definition is flexible to accommodate different sensor types (such as Bayer CFA sampling, Foveon, VGA Movie Mode).

## Faulty-Pixel Correction

Faulty-pixel correction in the CCDC module requires the camera driver to have information about the image-sensor faulty-pixel number and positions. This method leads to the best image quality. However, if the position of the faulty pixels is unavailable to the camera driver, it can apply another faulty-pixel correction algorithm in the preview module. This algorithm leads to lower-quality images.

The CCDC module implements an optional (CCDC\_FPC [15] FPCEN) faulty-pixel correction operation using a look-up table stored in external memory, which contains information about the horizontal and vertical positions of the pixels to be corrected, as well as the type of operation to be performed on the pixels. The CCDC\_FPC\_ADDR register specifies the starting address in memory for the faulty-pixel correction table.

---

**Note:** The memory address must be 64-byte-aligned (6 LSB are ignored).

---

---

**Note:** For YUV data, the faulty-pixel correction operation is not applicable and must be disabled/bypassed (CCDC\_FPC [15] FPCEN).

---

#### 1.4.4.3.4 Data Formatter, Lens-Shading Compensation, and Video-Port Interface

---

**Note:** For YUV data, the data formatter, lens-shading compensation, and video-port interface must be bypassed (CCDC\_FMTCFG [15] VPEN = 0x0 and CCDC\_SYN\_MODE [18] VP2SDR = 0x0).

---

The data-formatter module can be enabled to rearrange data after the faulty-pixel correction operation. It is intended to be used:

- When output data lines from the CCDC include pixels from multiple resolution lines. Internally, these sensors combine pixels from multiple horizontal lines into one output pseudoline.
- To smooth bandwidth. This helps reduce peak bandwidth when image cropping is used with the resizer.

The reformatter module performs the decomposition before the remainder of the normal CCDC processing stages.

The lens-shading compensation (LSC) module can be placed at two different locations:

- Before the data reformatter. It can only be used for Bayer sensors. The H3A video port gets the shading corrected image.
- After the data reformatter. This setup is required for non-Bayer sensors. Histogram and preview modules get the shading corrected image; however, H3A receives a non-corrected image.

Video-port/data-formatter output can also be saved to memory (instead of the RAW data). When CCDC\_SYN\_MODE [18] VP2SDR is set to 1, video-port data is sent to the output formatter. In addition, the CCDC\_SYN\_MODE [17] WEN bit must be enabled to store the output to memory.

The data-formatter and video-port interfaces are only 10 bits wide; therefore, the input data must be adjusted as it enters these modules. For flexibility, the bits to be retained can be selected by CCDC\_FMTCFG [14:12] VPIN.

The reformatter decomposes each input line into multiple output lines with new, internally generated HS/VS signals. The reformatter sends it to memory or to other camera ISP modules. These new HS/VS signals, rather than the original sensor HS/VS signals, then gate the downstream processing.

##### Conversion Area Select Parameters

When the data formatter is enabled, HS/VS signals are still generated as output (CCDC\_SYN\_MODE [16] VDHDEN = 0x1). The settings for these output signals are in the following fields:

- CCDC\_HD\_VD\_WID[27:16] HDW
- CCDC\_HD\_VD\_WID[11:0] VDW
- CCDC\_PIX\_LINES[31:16] PPLN
- CCDC\_PIX\_LINES[15:0] HLPRF

---

**Note:** These four registers are not used when HS/VS signals are input signals (CCDC\_SYN\_MODE [16] VDHDEN = 0x0).

---

---

**Note:** The settings reflect those for the sensor readout frame, not the resultant reformatted frame.

---

Registers CCDC\_FMT\_HORZ and CCDC\_FMT\_VERT control the interpretation of the input data frame when the data formatter is enabled.

Registers CCDC\_HORZ\_INFO, CCDC\_VERT\_START, and CCDC\_VERT\_LINES control the interpretation of the input data frame in normal mode (when the data formatter is not enabled).

Figure 1-19 shows the data formatter conversion area selection.

**Figure 1-19. Data Formatter Conversion Area Selection**

camisp-045

## Line Decomposition

When enabled, the reformatter can be configured to operate in line-alternating mode or program mode (CCDC\_FMTCFG [1] LNALT).

When line-alternating mode is enabled, the reformatter swaps even and odd lines. Basically, the 0<sup>th</sup> input line is output as the first line, the first input line is output as the 0<sup>th</sup> line, and so on. If this option is set, the start and number of lines for the formatter (CCDC\_VERT\_START and CCDC\_VERT\_LINES) must be even.

In program mode, or normal reformatter mode, the goal is to convert a single line of movie mode data to 1, 2, 3, or 4 lines of Bayer data. Each incoming line is decomposed according to the data-formatter settings and buffered into an internal line memory. The readout of the resultant multiple reformatted lines occurs as the next input line is being read from the sensor (and reformatted) to ensure that all output lines are fully constructed. The reformatter is subject to the restrictions listed in [Table 1-16](#).

**Table 1-16. Reformatter Output Limitations**

Number of Output Lines/Input Line	Max Pixels/Output Line
1	4 * 1376
2	2 * 1376
3	1 * 1376
4	1 * 1376

The reformatter derives its flexibility from supporting up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. Each of the 8 addresses supports either autoincrement or autodecrement. This capability is the key for supporting a multitude of readout patterns. The following examples show the programmability of the reformatter. Decomposition is controlled by defining the following parameters:

- CCDC\_FMTCFG [3:2] LNUM  
Number of lines into which each input line is to be decomposed
- CCDC\_FMTCFG [11:8] PLEN\_EVEN  
Number of program entries on even line
- CCDC\_FMTCFG [7:4] PLEN\_ODD  
Number of program entries on odd line
- CCDC\_FMT\_ADDRx (x=0:7)  
Output line in which the original pixel is to be placed, and initial address on the output line
- CCDC\_PRGEVEN0 or CCDC\_PRGEVEN1  
Program to be run on the even input lines
- CCDC\_PRGODD0 or CCDC\_PRGODD1  
Program to be run on the odd input lines

The CCDC\_FMT\_ADDRx registers define 8 address pointers (ADDR0 to ADDR7) that define which output line the input pixel belongs to, and the starting address (position) on that output line. Users can use up to 8 address pointers. The address pointer can be incremented or decremented, depending on the input pixel pattern. The address value computed should always follow the reformatter rules as formerly stated and should never be negative.

### **Lens-shading compensation**

- *Overview*

The purpose of the LSC function is lens-shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image must be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in external memory downsampled, and is accessed and upsampled by the LSC module before being applied to the pixel data.

The LSC function is useful for lens-shading compensation and for scene- and image-dependent lighting adjustment. Downsampled gain map reduces memory requirements for storage and bandwidth requirements for access of the gain maps in external memory.

- *Features supported*

- The memory stored gain map is MxN downsampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {4, 8, 16, 32, 64} independently and  $N \leq M$
- 8-bit entries in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0)
- Up to 10-bit unsigned image data input/output
- Up to 4096 x 3072 image dimension

- *Functional description*

The lens-shading correction module multiplies an image by a gain map that is stored downsampled in memory. The gain map can be dependent on aperture, lens-shading characteristics, and other photographic settings. It is generally used to correct the dim corner effect, but can also be used to implement adaptive lighting adjustment.

Separate horizontal and vertical sampling factors allow the lens-shading correction to work with the normal 1:1 aspect ratio image pixels, as well as tall-and-skinny pixels typical in the sensor's preview mode image data.

### 1.4.4.3.5 Output Formatter

The output formatter starts with a framing selection to limit the processing area by setting CCDC\_HORZ\_INFO, CCDC\_VERT\_START, and CCDC\_VERT\_LINES registers. This framing selection is applied in addition to the framing applied at the beginning and at the end of the data formatter operation if the video-port path to memory is selected (CCDC\_SYN\_MODE [18] VP2SDR).

The option to send the CCDC output to the resizer module (CCDC\_SYN\_MODE [19] SDR2RSZ) should not be used when in RAW data mode, because the resizer operates only on YUV format data. Use the preview module when resizing is desired in RAW data mode.

#### Low-pass filter (LPF)

An optional horizontal low-pass antialiasing filter can be applied (CCDC\_SYN\_MODE [14] LPF) after reframing. The low-pass filter consists of a simple 3-tap (1/4, 1/2, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

---

**Note:** For YUV data, the LPF must be disabled (CCDC\_SYN\_MODE [14] LPF = 0x0).

---

#### Culling

An optional culling operation can be enabled (CCDC\_CULLING register). This operation allows selected pixel data to be culled (deleted) from a line (CCDC\_CULLING [31:24] CULHEVN, CCDC\_CULLING [23:16] CULHODD - 8-bit repeating mask, one per field) and selected lines to be culled from a frame (CCDC\_CULLING [7:0] CULV).

Figure 1-20 is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, CCDC\_CULLING = 0x239A0066:

- CCDC\_CULLING [31:24] CULHEVN = 0x23
- CCDC\_CULLING [23:16] CULHODD = 0x9A
- CCDC\_CULLING [7:0] CULV = 0x66

---

**Note:** Culling can be used with YUV data, but care must be taken to preserve the YUV422 output format.

---

**Figure 1-20. CCDC/Culling: Example for Decimation Pattern**

	LSB						MSB	
CCDC_CULLING [31:24]	0	0	1	0	0	0	1	1
CULHEVEN

4 <sup>th</sup> line								0
5 <sup>th</sup> line								1
6 <sup>th</sup> line								1
7 <sup>th</sup> line								0

CCDC\_CULLING[7:0]  
CULV

camisp-048

### A-Law compression

An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied (CCDC\_ALAW [3] CCDBTL) as the final processing stage. Using this causes data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected (CCDC\_ALAW [2:0] GWDI).

The preview module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

---

**Note:** A-Law compression should not be used (CCDC\_ALAW [3] CCDBTL = 0) with YUV data.

---

Figure 1-21 show the A-Law table.

**Figure 1-21. A-Law Table**

## Line-Output Control

**Note:** Line-output control can be used with YUV data.

The CCDC final stage is line-output control, which controls how the input sensor lines are written to memory. The value of CCDC\_SDR\_ADDR [31:0] ADDR defines the starting address where the frame should be written in memory. The value of CCDC\_HSIZE\_OFF [15:0] LNOFST defines the distance between two lines for each output line to memory. The starting address and line-offset values should be aligned to 32-byte boundaries; that is, either 16 or 32 pixels, depending on the CCDC\_SYN\_MODE [11] PACK8 setting. Register CCDC\_SDOFST can be used to define additional offsets, depending on the field ID and even/odd line numbers. This provides a means to deinterlace an interlaced 2-field input and to invert an input image vertically. See [Table 1-17](#).

**Table 1-17. CCDC\_SDOFST Description**

Register	Description
CCDC_SDOFST [14] FIINV	Invert interpretation of the field ID signal
CCDC_SDOFST [13:12] FOFST	Offset, in lines, of field = 1
CCDC_SDOFST [11:9] LOFST0	Offset, in lines, between even lines on even fields (field 0)
CCDC_SDOFST [8:6] LOFST1	Offset, in lines, between odd lines on even fields (field 0)
CCDC_SDOFST [5:3] LOFST2	Offset, in lines, between even lines on odd fields (field 1)
CCDC_SDOFST [2:0] LOFST3	Offset, in lines, between odd lines on odd fields (field 1)

## Line output control: 2D addressing example

The CCDC memory port can be configured to write a subimage into a bigger image buffer. This feature is useful for overlaying a video preview flow with the rest of the display. To use this feature, the CCDC\_SDR\_ADDR [31:0] ADDR register points to the first pixel to write and the CCDC\_SDOFST [13:12] FOFST is set to the size of one line of the destination buffer. See [Figure 1-22](#).

**Figure 1-22. CCDC 2D Addressing Mode**

camisp-107

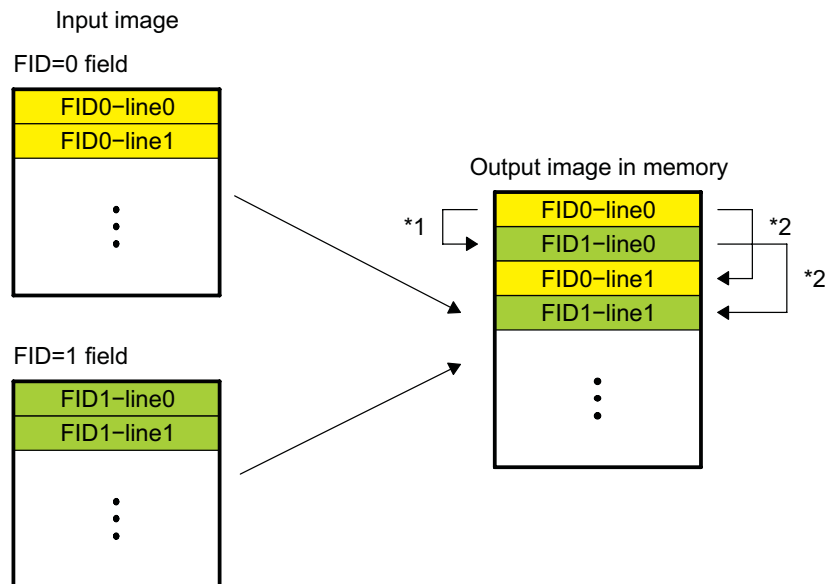

**Note:**

- This mode can be used only when the source and destination buffers use the same image format.
- 2D addressing is also supported by other camera ISP modules.

**Line-output control: Examples**

Figure 1-23 and Figure 1-24 show examples of line-output control for frame format conversion and sample formats of input and output images.

**Figure 1-23. CCDC/Line-Output Control: Frame Format Conversion**

\*1 - CCDC\_SDOFST[13:12] = 00b, +1 line for FID = 1 line

**Figure 1-24. CCDC/Line-Output Control: Sample Formats of Input and Output Images**

camisp-051

## Output format

The data bits comprising each pixel are stored in the lower bits of a 16-bit memory word and the unused bits are zero-filled. The memory data format is shown in [Table 1-18](#). The format is determined by the CCDC\_SYN\_MODE [10:8] DATSIZ field.

If 8-bit data is input, or if A-Law compression is applied, the data can be packed through the CCDC\_SYN\_MODE [11] PACK8 setting so that a pixel occupies only 8 bits.

Data is output to memory only when enabled through the CCDC\_SYN\_MODE [17] WEN setting. The pixels are ordered in little-endian format.

**Table 1-18. Memory Output Format for RAW Data**

	Upper word		Lower word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
16 bit	Pixel 1		Pixel 0	
15 bit	0	Pixel 1	0	Pixel 0
14 bit	0	Pixel 1	0	Pixel 0
13 bit	0	Pixel 1	0	Pixel 0
12 bit	0	Pixel 1	0	Pixel 0
11 bit	0	Pixel 1	0	Pixel 0
10 bit	0	Pixel 1	0	Pixel 0
9 bit	0	Pixel 1	0	Pixel 0
8 bit	0	Pixel 1	0	Pixel 0
8-bit packed	Pixel 3	Pixel 2	Pixel 1	Pixel 0

**Note:** YUV data is stored in memory in packed YUV422 mode, using two pixels per 32 bits, as shown in [Table 1-19](#).

**Table 1-19. Memory Output Format for YUV Data**

Memory Address	Upper word		Lower word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

#### 1.4.4.4 DMA

The CCDC module is a master. It has its own address generator and sends addresses and data to the central-resource shared-buffer logic. The central-resource shared-buffer logic arbitrates the data requests and generates the bursts to memory.

#### 1.4.4.5 Memories

The CCDC module has one memory:

- REFORMATTER BUFFER:  $3 \times 1376 \times 40$  bits
- LSC PREFETCH BUFFER:  $1536 \times 32$  bits

### 1.4.5 IPIPE

#### 1.4.5.1 Preview Engine Features

The preview module is responsible for transforming data from a RAW image sensor into YUV422 data that is amenable to still-image encoding, video encoding, or display. It supports the following features:

- Flexible input: Module input data can come from the RAW image sensor (10 bits) or from memory (8 or 10 bits).
- Flexible input formats: Bayer RGB color filter array, complementary-color filter array, Foveon sensors, Honeycomb sensors, SMIA sensors
- Horizontal averaging by a factor of 2, 4, or 8 in the horizontal direction. The preview module can output a maximum of only 3312 pixels horizontally due to fixed memory-line sizes.
- A-Law decompression: Transforms nonlinear 8-bit data to 10-bit linear data. The CCDC module can perform A-Law compression.
- Noise reduction and faulty-pixel correction:
  - Dark-frame capture and subtraction
  - Horizontal median filter
  - Programmable noise filter:  $3 \times 3$  kernel of same color pixels
  - Couplet faulty-pixel correction
- Digital gain and white balance
- Programmable CFA interpolation that operates on a  $5 \times 5$  grid
- Programmable RGB-to-RGB blending matrix: 9 coefficients for the  $3 \times 3$  matrix
- Programmable gamma correction: 1024 entries for each color held in local memory
- Programmable RGB-to-YUV color conversion: 9 coefficients for the  $3 \times 3$  matrix
- Luminance enhancement (nonlinear), chrominance suppression and offset

The input memory address (PRV\_RSDR\_ADDR) and line offset (PRV\_RADR\_OFFSET) registers should be aligned on 32-byte boundaries when the input source is set to memory. The dark-frame input address (PRV\_DSDR\_ADDR) and line offset (PRV\_DRKF\_OFFSET) should also be aligned on 32-byte boundaries when the dark-frame subtract function is enabled.

When the input source is memory, the preview engine always operates in one-shot mode. After enabling the preview engine and processing a frame, the enable bit is turned off and it is up to firmware to reenale it to process the next frame from memory.

When the input source is the CCDC, the preview engine can be configured to operate in one-shot mode or continuous mode (PRV\_PCR [3] ONESHOT).

The SBL image data read port is shared between the preview module. When the image is read from memory, the read port must be affected to the preview receiver module by writing 0 into the ISP\_CTRL [27] SBL\_SHARED\_RPORTA.

### 1.4.5.1.3 Input Formatter/Averager

Preview-engine output is limited to 3312 pixels per horizontal line due to line memory-width restrictions in the noise filter and CFA interpolation blocks. To support sensors that output more than 3312 pixels per line, an averager is incorporated to downsample by factors of 1 (no averaging), 2, 4, or 8 in the horizontal direction (PRV\_AVE [1:0] COUNT). The horizontal distance between two consecutive pixels of the same color to be averaged is selectable from among 1, 2, 3, or 4 for both even (PRV\_AVE [3:2] EVENDIST) and odd (PRV\_AVE [5:4] ODDDIST) lines. This must be configured to match the input pattern type.

Valid output of the input formatter/averager is either 8 or 10 bits wide.

Figure 1-26 shows the horizontal distances for different patterns.

**Figure 1-26. Horizontal Distances for Different Patterns**

### 1.4.5.1.4 Dark-Frame Write

The preview engine is capable of capturing and saving a dark frame to memory instead of performing conventional processing steps (PRV\_PCR [7] DRKFCAP).

This dark frame can later be subtracted from the RAW image data to eliminate the repeatable baseline noise level in the frame.

Each input pixel is written as an 8-bit value; if the input pixel value is greater than 255, it is saturated to 255. If a dark pixel is greater than 255, it is more likely to be faulty, and can be corrected by the faulty-pixel correction module in the CCDC. If properly corrected, the value must be less than 255 when it reaches the preview engine.

The PRV\_WSDR\_ADDR and PRV\_WADD\_OFFSET registers must be used to indicate the output address and line offset, respectively, of the dark-frame output in memory.

### 1.4.5.1.5 Inverse A-Law

To save memory capacity and bandwidth, the CCDC includes an option to apply 10-bit to 8-bit A-Law compression and to pack the sensor data to 1 byte per pixel. To process this data correctly, the inverse A-Law block is provided to decompress the 8-bit nonlinear data back to 10-bit linear data if enabled (PRV\_PCR [5] INVALAW). Even if the inverse A-Law block is not enabled, but the input is still 8 bits (PRV\_PCR [4] WIDTH), the data is left shifted by 2 to make it 10-bit data. If the input is 10 bits wide, no operation is performed on the data.

---

**Note:** When A-Law compression in CCDC is enabled during dark-frame write, it must be enabled when the stored dark frame is used.

---

#### 1.4.5.1.6 Dark-Frame Subtract or Shading Compensation

The preview engine can fetch a dark frame containing 8-bit values from memory (8 bits in input are converted internally to 10 bits by adding two zeros to the left) and subtracting it, pixel by pixel, from the incoming input frame (PRV\_PCR [6] DRKFEN). This function removes pattern noise in the sensor. The output of the dark-frame subtract operation is 10 bits wide (U10Q0).

There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the PRV\_PCR [31] DRK\_FAIL status bit is set to indicate a fail.

Instead of performing the dark-frame subtract, the preview engine can perform lens-shading compensation (if PRV\_PCR [21] SCOMP\_EN is set along with PRV\_PCR [6] DRKFEN). In this case, the 8-bit unsigned value fetched from memory is multiplied by the incoming pixel, and the result is right-shifted by the number of bits specified by the PRV\_PCR [24:22] SCOMP\_SFT parameter (0-7 bits).

The SBL data read port is shared between the CCDC and preview module. The read port must be affected to the preview module by writing 0 into the ISP\_CTRL [28] SBL\_SHARED\_RPORTB. Programmers must ensure that the CCDC module does not use this port before switching to the preview module.

#### 1.4.5.1.7 Horizontal Median Filter

The preview engine contains a horizontal median filter that can help reduce temperature-induced noise effects. The horizontal median filtering operation, shown in , calculates the absolute difference between the current pixel (I) and pixel (I-X) and between the current pixel (I) and pixel (I+X). If the absolute difference exceeds a specified threshold and the sign of the differences is the same, the average of pixel (I-X) and pixel (I+X) replaces pixel (I). The horizontal median filter's threshold is configurable (PRV\_HMED [7:0] THRESHOLD), and the horizontal median filter can be either enabled or disabled (PRV\_PCR [8] HMEDEN). The horizontal distance (X) between two consecutive pixels can be either 1 or 2 pixels for both even (PRV\_HMED [8] EVENDIST) and odd (PRV\_HMED [9] ODDDIST) lines. The input and output of the horizontal median filter are 10 bits wide (U10Q0).

---

**Note:** Line-width reduction: If the horizontal median filter is enabled, the preview engine reduces the length of the output line of this stage by 4 pixels (2 starting pixels -left edge and 2 ending pixels -right edge). For example, if the input size is 656x490 pixels, the output is 652x490 pixels. There is no truncation of input data line if this block is disabled.

---

#### 1.4.5.1.8 Noise Filter and Faulty Pixel Correction

##### 1.4.5.1.8.1 Overview

The noise filter and couplet defect correction (CDC) operate on the same 3x3 matrix of same color pixels. Both functions can be enabled separately using the PRV\_PCR [27] DCOREN and PRV\_PCR [9] NFEN bits.

The faulty pixel correction function replaces the central pixel (x0) with one of the neighbors (x1-x8) in the following cases:

- When it has been identified as faulty.
- When the feature is enabled.

The noise filter modifies the central pixel when it is enabled. The neighbors used by the algorithm have not been corrected by the faulty pixel stage. However, they are not being used by the noise filter because they are far apart from the central pixel. In other words, the difference between the pixel intensities is above a user-configurable threshold. The algorithm chooses whether noise filter or faulty pixel correction is used.

- When no faulty pixels are detected, only the noise filter modifies the central pixel.

- When one neighbor is a faulty pixel, the CDC stage does not correct it. However, the faulty pixel is not used by the noise filter because it is far apart from the central pixel.
- When the central pixel is faulty, it is replaced by the CDC stage. The central pixel is then filtered by the noise filter stage,
- When the central pixel and one of its neighbors are faulty, the CDC replaces the central pixel and the noise filter does not use the other faulty pixel.
- However, when the central pixel and two or more neighbors are faulty, no correction can be done by the CDC stage and the noise filter uses faulty pixels. Those defects are not corrected.

#### 1.4.5.1.8.2 Same Color Pixel Extraction and Cropping

The pixel extraction stage assumes that the horizontal and vertical distances between same color pixels is always 2.

Foveon sensors that follow the RGBRGB color pattern have a horizontal distance of 3. Therefore, they are not supported and this function must be disabled when using these sensors.

If either or both features are enabled, the preview engine reduces the output of this stage by 4 pixels in each line (2 starting pixels – left edge and 2 ending pixels – right edge) and 4 lines in each frame (2 starting lines – top edge and 2 ending lines – bottom edge). For example, if the input size is 656x490 pixels, the output is 652x486 pixels. There is no chopping of data if this block is disabled.

#### 1.4.5.1.8.3 Defect Correction

The camera ISP supports single and couplet defect correction. The advantage of those algorithms, compared to the faulty pixel correction implemented inside the CCDC module, is that it does not have to know the positions of the faulty pixels.

The defect-correction algorithms are based on on-the-fly min/max exclusion. Both algorithms are mutually exclusive.

##### 1.4.5.1.8.3.1 Single Defect Correction

Each pixel is compared with the surrounding 8 pixels in the same color plane. If the center pixel is larger than the maximum among them, the output is the second largest value. If the center pixel is the minimum, it is replaced by the second smallest value. If the center pixel is neither the maximum nor minimum, the center pixel is the output.

The single defect correction mode is entered when the following bits are set:

- PRV\_PCR [27] DCOREN = 1
- PRV\_PCR [28] DCOR\_METHOD = 0
- PRV\_CDC\_THRx [9:0] DETECT = 0
- PRV\_CDC\_THRx [25:16] CORRECT = 1023

##### 1.4.5.1.8.3.2 Couplet Defect Correction (CDC)

The defect-correction module also supports couplet defect correction (MinMax2 defect-correction). In MinMax2 defect-correction, the center pixel is compared with the 2<sup>nd</sup> maximum and the 2<sup>nd</sup> minimum pixel among the surrounding 8 pixels. If the center pixel is larger than the 2<sup>nd</sup> maximum signal by more than thrD (PRV\_CDC\_THRx [9:0] DETECT x = 0, 1, 2, 3 depending on color), the center pixel is considered as a defect pixel. Then, the center pixel is replaced with the maximum value of surrounding pixels, unless the difference between the maximum pixel and the 2<sup>nd</sup> maximum value is larger than thrC (PRV\_CDC\_THRx [25:16] CORRECT x = 0, 1, 2, 3 depending on color). In this case, the center pixel is replaced with the 2<sup>nd</sup> maximum pixel.

#### 1.4.5.1.8.4 Noise Filter

The basic concept of the 2D noise filter is *area averaging by excluding far-apart-value neighbors*. This algorithm uses the following two tables:

- Threshold table (10 bits, 32 entries), which is used in the filtering algorithm
- Strength table (5 bits, 32 entries), which stores averaging weight

#### 1.4.5.1.9 White Balance

The white-balance module has a digital gain adjuster and a white-balance adjuster. In the digital gain adjuster (PRV\_WB\_DGAIN [9:0] DGAIN), RAW data is multiplied by a fixed-value gain, regardless of the color of the pixel to be processed.

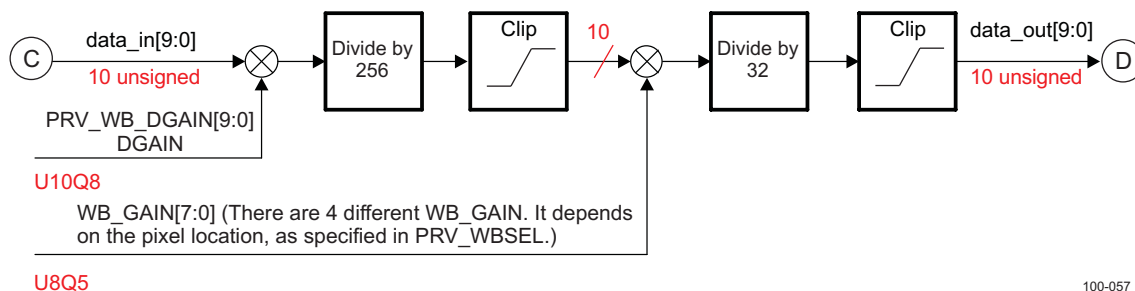

In the white-balance gain adjuster (PRV\_WBGAIN), RAW data is multiplied by a selected gain corresponding to the color of the processed pixel.

For non-Foveon sensors (PRV\_PCR [14:11] CFAFMT different from 2 or 5), the white-balance gain can be selected from four 8-bit values, depending on the position of the current pixel. First horizontal and vertical positions are computed modulo 4 starting from the first received pixel. This position is used to fetch the white-balance gain index from the PRV\_WBSEL register. This index is then used to fetch the corresponding white-balance gain from the PRV\_WBGAIN register.

If the input is from a Foveon sensor (PRV\_PCR [14:11] CFAFMT equals to 2 or 5), the white-balance gain is selected by using modulo-3 arithmetic. If the Foveon pattern is RGBRGB, modulo-3 arithmetic is used in the horizontal pixel counts. If the Foveon pattern is RRR GGG BBB, modulo-3 arithmetic is used in the vertical line counts.

Figure 1-27 is the block diagram of the white-balance module.

Figure 1-27. White Balance Functional Models

100-057

#### 1.4.5.1.10 CFA Interpolation

The CFA function is responsible for providing full RGB data for each pixel. Depending on sensor type and configuration, interpolation and/or rephasing are required.

The CFA function can be enabled (PRV\_PCR [10] CFAEN) and configured to different interpolation modes (PRV\_PCR [14:11] CFAFMT).

For example, when CFAFMT=1, the sensor sends 2 samples for each physical location. For odd lines, it sends R, G, and B must be interpolated. For even lines, it sends B, G, and R must be interpolated.

##### 1.4.5.1.10.1 CFA for Bayer Modes

In Bayer modes, the CFA interpolation block is responsible for populating the missing color pixels at a given location, resulting in a 3-color RGB pixel. It does this by interpolating data from neighboring pixels of the same color. See Table 1-20.

Table 1-20. CFA-Supported Bayer Modes

Mode	PRV_PCR [14:11] CFAFMT	Sensor Sent Colors per Location	Interpolated Colors per Location
Generic Bayer	0	1	2
N + 1	1	2	1
N + 2	3	4	0

In the generic mode, CFA interpolation is implemented using programmable filter coefficients that operate on a 5×5 grid:

- Each coefficient is coded in S8Q6 format.
- Each output color , G, and B) has its own set of coefficients.
- There are 4 phases. Each pixel is associated with a phase.
- Different sets of filter coefficients are provided, depending on the tendency (gradient in the data: horizontal, vertical, or neutral).
- So there are 3 color × 4 phase × 3 tendencies × 16 taps = 576 coefficients (each coefficient is 8 bits wide).

---

**Note:** Coefficients are based on sensor type. However, users can use a different methods of defining an optimal coefficient set.

---

#### 1.4.5.1.10.2 CFA Options

If the CFA interpolation block is disabled, the same input pixel is broadcast to all three output pixels.

---

**Note:** Image-size reduction: If CFA interpolation is enabled, the preview engine reduces the output of this stage. Two pixels/line in the left, right, top, and bottom edges are truncated in the Bayer/conventional and other modes.

---

If the CFA format is 2× downsampling in both horizontal and vertical directions, or if the sensor is in Foveon format (serial RGB and RRRR GGGG BBBB patterns), only 2 lines at the top and bottom of the image are truncated. The two left- and right-most pixels are processed.

#### 1.4.5.1.11 Black Adjustment

The CFA interpolation output is three pixels (red, blue, and green values) and this is fed as input to the black-adjustment module, which performs the following calculation for an adjustment of each color level:

$$data\_out = data\_in + bl\_offset$$

#### 1.4.5.1.12 RGB Blending

The RGB2RGB blending module has a general 3×3 square matrix and redefines the RGB data from the CFA interpolation module, which can be used as a function of a color correction. This is programmable (PRV\_RGB\_MAT1, PRV\_RGB\_MAT2, PRV\_RGB\_MAT3, PRV\_RGB\_MAT4, PRV\_RGB\_MAT5, PRV\_RGB\_OFF1, & PRV\_RGB\_OFF2) so that the color spectrum of the sensor can be adjusted to the human color spectrum. The input is signed 11 bits and the output is unsigned 10 bits. The following calculation is performed in this module:

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} MTX\_RR & MTX\_GR & MTX\_BR \\ MTX\_RG & MTX\_GG & MTX\_BG \\ MTX\_RB & MTX\_GB & MTX\_BB \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} MTX\_OFFR \\ MTX\_OFFG \\ MTX\_OFFB \end{bmatrix}$$

camisp-E094

Gains are in S12Q8 format, and offsets are in S10Q0 format.

---

**Note:** All blending matrix coefficients are equal to 1 (256 in S12Q8 coding) after reset. The following computation must be performed to bypass the RGB to RGB blending step:

---

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

camisp-E161

That leads to:

$$\begin{aligned} MTX_{RR} &= MTX_{GG} = MTX_{BB} = 256 \\ others &= 0 \end{aligned}$$

#### 1.4.5.1.13 Gamma Correction

Gamma correction is performed on each of the R, G, and B pixels separately by indexing programmable gamma look-up tables. Each table has 1024 8-bit entries. The input data value is used to index into the table and the table content is the output.

The gamma table can be bypassed (PRV\_PCR [26] GAMMA\_BYPASS). In this case, the output of the gamma correction is the 8 MSB of the 10-bit input. The gamma table can be written only while the preview engine is disabled.

##### 1.4.5.1.13.1 RGB-to-YCbCr Conversion

The RGB-to-YCbCr conversion module has a 3×3 square matrix and converts the RGB color space of the image data into the YCbCr color space. In this module, the following calculation is performed using the contents of the PRV\_CSC0, PRV\_CSC1, PRV\_CSC2, and PRV\_CSC\_OFFSET registers:

$$\begin{bmatrix} Y \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} CSCRY & CSCGY & CSCBY \\ CSCRCB & CSCGCB & CSCBCB \\ CSCRCR & CSCGCR & CSCBCR \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} YOFST \\ OFSTCB \\ OFSTCR \end{bmatrix}$$

camisp-E095

Gains are in S10Q8 format, and offsets are in S8Q0 format for chroma and U10Q0 for luma.

**Note:** Program the following values after reset for correct color conversion:

- PRV\_CSC2 [19:10] CSCGCR = 0x39E
- PRV\_CSC2 [9:0] CSCRCR = 0x080

##### 1.4.5.1.13.2 Nonlinear Luminance Enhancement

Nonlinear luminance enhancement functions as an edge enhancer (crossed in the horizontal direction). It can be enabled or disabled using the PRV\_PCR [15] YNENHEN parameter. If it is enabled, a look-up table with 127 20-bit entries must be programmed. Each entry contains a 10-bit signed offset value in the MSBs, and a 10-bit signed slope in the LSBs.

Table 1-21 lists the format of each entry.

**Table 1-21. Nonlinear Luminance-Enhancement Table Entry Format**

MSB	LSB
19	9
10	0
OFFSET	SLOPE

### 1.4.5.1.13.2.1 Chrominance Suppression

Occasionally, in very bright portions of an image, only one or two of the color channels are saturated, while the remaining channel(s) are not. This can lead to a false-color effect. One common example is the appearance of pink where white should be. Chrominance suppression can be used to correct this issue.

Chrominance suppression can be enabled or disabled using the PRV\_PCR [16] SUPEN parameter. False-color pixels can also be introduced on edges crossed in the horizontal direction by the CFA interpolation function. The luminance value used in the calculation can be configured as the luminance value or the high-pass-filtered version of the luminance value to find the edge information in the horizontal direction (PRV\_CSUP [16] HPYF). The chrominance suppression threshold and gain can be set in the PRV\_CSUP [15:8] CSUPTH (U8Q0) and PRV\_CSUP [7:0] CSUPG (U8Q8) fields, respectively.

### 1.4.5.1.13.2.2 Contrast and Brightness

The luminance component can be adjusted for contrast (scaling/multiplication) and brightness (offset/addition). Contrast is set in the PRV\_CNT\_BRT [15:8] CNT field (U8Q4 precision), and brightness is set in the PRV\_CNT\_BRT [7:0] BRT field (U8Q0 precision).

### 1.4.5.1.13.2.3 Downsampling and Output Clipping

The 4:2:2 conversion module converts image data to YCbCr-4:2:2 format by averaging every other Cb and Cr component in the horizontal direction. Before outputting the data, the preview engine performs clipping on the YCC components separately. The minimum and maximum threshold values for the Y and C values are specified using the PRV\_SETUP\_YC register. If no clipping is required, the register must be set to its reset values of 0xFF for the maximum Y and C values, and 0 for the minimum Y and C values.

### 1.4.5.1.14 Write-Buffer Interface

The output of the preview engine may be passed directly to the resizer (PRV\_PCR [19] RSZPORT) and/or written to memory (PRV\_PCR [20] SDRPORT).

If the output is written to memory, the write address (PRV\_WSDR\_ADDR) and line offset (PRV\_WADD\_OFFSET) must be on 32-byte boundaries. The output format of the YCC data is programmable by setting the PRV\_PCR [18:17] YCPOS parameter.

The final width and height of the output vary depending on which processing functions are enabled. [Table 1-22](#) indicates how many edge pixels/lines are truncated by enabling certain modules in the preview engine. These values must be subtracted from the input height and width after the averager to determine the size of preview-engine output.

**Table 1-22. Image Cropping by Preview Functions**

Image Cropping by Preview Functions		
Function	Pix/Line	Lines
Horizontal median filter	4	0
Noise filter	4	4
CFA (Bayer, Fuji, or Sony)	4	4
CFA (Foveon or 2x down sampling)	0	2
Color suppression OR luminance enhancement	2	0
Maximum total	14	8

---

**Note:** Different CFA modes are mutually exclusive

---

## 1.4.5.2 Resizer

### 1.4.5.2.1 Features

The resizer module enables image upsampling and downsampling, see [Table 1-23](#). The following features are supported:

- Flexible input sources:
  - Preview module: enables on-the-fly processing.
  - Memory: enables differed processing.
- Flexible input format:
  - YUV422 packed data (16 bits)
  - Color-separate data (8 bits). The data must be contiguous in memory. The input source for the data must be the memory: not available for on-the-fly processing.
  - Same output format as input
- Upsampling: Up to 4 $\times$ . Enables digital zoom:
  - General polyphase filter:
    - Ratio of 1 $\times$  to 4 $\times$ : 4 taps (horizontal and vertical) and 8 phases
- Downsampling: Down to 0.25 $\times$ :
  - General polyphase filter:
    - Ratio of 0.25 $\times$  to 0.5 $\times$ : 7 taps (horizontal and vertical) and 4 phases
    - Ratio of 0.5 $\times$  to 1 $\times$ : 4 taps (horizontal and vertical) and 8 phases
- Constraints:
  - The following input width (IW) and output width (OW) constraints must be obeyed due to limited on-chip memory resources.

**Table 1-23. Resizer Use Constraints**

Resizer Use Constraints			Horizontal Resizer Ratio	
			0.25 $\times$ to 0.5 $\times$	0.5 $\times$ to 4 $\times$
			7 taps	4 taps
Vertical resizer ratio	0.25 $\times$ to 0.5 $\times$	7 taps	OW $\leq$ 1650	OW $\leq$ 1650
	0.5 $\times$ to 4 $\times$	4 taps	OW $\leq$ 3312	OW $\leq$ 3312

- The horizontal resizer output rate must not exceed half the functional clock; that is, at 166-MHz functional clock, the horizontal resizer output rate must not exceed 83M pixels/s. This limitation applies only for the on-the-fly processing input source.
- Flexible resizing ratios: Independent resizing factors for the horizontal and vertical directions. The applicable ratio is 256/N, with N ranging from 64 to 1024.
- Programmable luminance enhancer
- Continuous and one-shot operation

### 1.4.5.2.2 Block Diagram

The resizer module performs either upsampling (digital zoom) or downsampling on image/video data within a range of 0.25 $\times$  to 4 $\times$  resizing. The input source can be sent to either the preview engine/CCDC or memory, and the output is sent to memory.

The resizer module performs horizontal resizing, then vertical resizing, independently. Between them there is an optional edge-enhancement feature. This process is shown in [Figure 1-28](#).

**Figure 1-28. Resizer Process**

### 1.4.5.2.3 Input and Output Interfaces

The input source can be sent to either the preview engine/CCDC or memory (RSZ\_CNT [28] INPSRC). The input width (RSZ\_IN\_SIZE [12:0] HORZ) must be at least 32 pixels.

#### 1.4.5.2.3.1 Preview Engine/CCDC Input Mode

In the preview engine/CCDC input mode, internal hardware synchronization signals define input frames. The horizontal starting byte (RSZ\_IN\_START [12:0] HORZ\_ST) and vertical starting line (RSZ\_IN\_START [28:16] VERT\_ST) define a starting pixel with respect to the upper-left corner of an input image (signaled through horizontal and vertical synchronization signals). The input width and height in the RSZ\_IN\_SIZE register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

**Note:** Care must be taken to ensure that the input sizes specified by the RSZ\_IN\_START and RSZ\_IN\_SIZE registers are less than or equal to the output from the preview engine or CCDC; otherwise, incorrect hardware operation may occur.

RSZ\_SDR\_INADD and RSZ\_SDR\_INOFF must be programmed to be 0x0 in this mode.

Also, the output ports of the CCDC (CCDC\_SYN\_MODE [19] SDR2RSZ) and preview engine (PRV\_PCR [19] RSZPORT) to the resizer must be configured so that only one of them is enabled. If both are enabled, the CCDC gains control of this interface.

If input is from the CCDC, the output of the CCDC must be in YUV422 format (the resizer does not support resizing RAW data from the CCDC).

#### 1.4.5.2.3.2 Memory-Input Mode

In memory-input mode, the memory address in RSZ\_SDR\_INADD points to the 32-byte-aligned memory address where the starting pixel resides.

The horizontal starting pixel (RSZ\_IN\_START [12:0] HORZ\_ST) defines a starting pixel within that 32-byte alignment; HORZ\_ST is constrained to 0...15 for the 422 format, and 0...31 for the color-separated format.

The vertical starting pixel (RSZ\_IN\_START [28:16] VERT\_ST) must be zero in memory-input mode. The RSZ\_SDR\_INOFF register specifies the address offset between rows of input data. The input width and height in the RSZ\_IN\_SIZE register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

Figure 1-29 shows the resizer in memory-input mode.

Figure 1-29. Resizer in Memory-Input Mode

camisp-115

#### 1.4.5.2.3.3 Output Interface

In both input modes, the RSZ\_OUT\_SIZE register specifies output width/height, the RSZ\_SDR\_OUTADD register specifies output starting pixel (upper-left corner) memory address, and the RSZ\_SDR\_OUTOFF register specifies memory address offset between the beginning of output rows. The resizer output always goes to memory.

**Note:** RSZ\_SDR\_INADD, RSZ\_SDR\_OUTADD, RSZ\_SDR\_INOFF, and RSZ\_SDR\_OUTOFF must be 32-byte-aligned; the lower 5 bits of the byte address are assumed zero.

Output-width constraints: The output width (RSZ\_OUT\_SIZE [11:0] HORZ) must be at least 16 pixels, and be even (so that the same number of Cb and Cr components is outputted). Due to the vertical memory size constraint, the output width (RSZ\_OUT\_SIZE [11:0] HORZ) cannot be greater than:

- 3312 pixels if the vertical resizing ratio is between  $\times$  and  $4\times$  ((RSZ\_CNT [19:10] VRSZ + 1) = 512)
- 1650 pixels wide if the vertical resizing ratio is between  $\times$  and  $1/4\times$  ((RSZ\_CNT [19:10] VRSZ + 1) > 512)

#### 1.4.5.2.4 Horizontal and Vertical Resizing

In the rest of this section:

- HRSZ is used for RSZ\_CNT [9:0] HRSZ + 1
- VRSZ is used for RSZ\_CNT [19:10] VRSZ + 1

The resizer module can upsample or downsample image data with independent resizing factors in the horizontal and vertical directions. The HRSZ and VRSZ parameters can range from 64 to 1024 to give a resampling range from  $4\times$  to  $0.25\times$  (256/HRSZ or 256/VRSZ).

The resizer module uses the same resampling algorithm for the horizontal and vertical directions.

The resizing/resampling algorithm uses a programmable polyphase sample rate converter (resampler). The polyphase filter coefficients are programmable so that any user-specified filter can be implemented.

Figure 1-30 shows a general sample-rate converter where the resampling rate is equal to L/M.

**Figure 1-30. Typical Sample-Rate Converter**

L phases are used in a typical polyphase implementation. The resizer module, however, fixes the number of phases to 8 for a resizing range of  $\times \sim 4\times$  ( $RSZ = 64 \sim 512$ ), or 4 for a resizing range of  $1/4\times \sim 1/2\times$  ( $RSZ = 513 \sim 1024$ ). In this way, the upsampling value (L) is fixed to either 8 or 4, and the downsampling value (M) is based on RSZ. To achieve a resizing ratio of  $256/RSZ$ , the downsampling value (M) is equal to  $(P \times RSZ)/256$ , where P is the number of phases. Figure 1-31 shows the resizer functionality.

**Figure 1-31. Resizer Functionality**

Figure 1-32 shows a model of the resolution of the noninteger downsampling ratio. The interpolated output from the filter is upsampled and replicated 256/P times before it is downsampled by the RSZ factor.

**Figure 1-32. Resizer Approximation Scheme**

This implementation means that a resizing ratio with  $256/RSZ$  times the input size can be obtained. However, each output pixel is rounded to the nearest interpolated output of  $1/P$  input-pixel precision. The polyphase filter coefficients are programmable so that any user-specified filter can be implemented. It is recommended that coefficient sets be chosen to implement a sample rate converter where a low-pass filter is used, with a cutoff frequency as shown in Figure 1-33.

**Figure 1-33. Cutoff Frequency for Low-Pass Filter**

$$\omega_c = \min\left(\frac{\pi}{P}, \frac{\pi}{\frac{P \times RSZ}{256}}\right)$$

camisp-E126

If polyphase resampling is used, all upsampling factors can share the same set of coefficients. However, a different coefficient set is required when changing between 8-phase and 4-phase modes, and with different downsampling factors.

32 programmable coefficients are available for the horizontal direction (registers RSZ\_HFILT10 to

RSZ\_HFILT3130) and another 32 programmable coefficients are available for the vertical direction (registers RSZ\_VFILT10 to RSZ\_VFILT3130). The 32 programmable coefficients are arranged as either 4 taps and 8 phases for the resizing range of  $\times \sim 4\times$  (RSZ = 64 ~ 512), or 7 taps and 4 phases for a resizing range of  $1/4\times \sim 1/2\times$  (RSZ = 513 ~ 1024)(RSZ is either HRSZ or VRSZ). [Table 1-24](#) shows the arrangement of the 32 filter coefficients. Each tap is arranged in S10Q8 format.

**Table 1-24. Arrangement of the Filter Coefficients**

Filter Coefficient	0.5x to 4x		0.24x to ~0.5x	
	Phase	Tap	Phase	Tap
0	0	0	0	0
1		1		1
2		2		2
3		3		3
4	1	0		4
5		1		5
6		2		6
7		3		Not used
8	2	0	1	0
9		1		1
10		2		2
11		3		3
12	3	0		4
13		1		5
14		2		6
15		3		Not used
16	4	0		
17		1		
18		2		
19		3		
20	5	0		
21		1		
22		2		
23		3		Not used
24	6	0	3	0
25		1		1
26		2		2
27		3		3
28	7	0		4
29		1		5
30		2		6
31		3		Not used

The indexing scheme of coefficients is oriented for dot-product (or inner product), rather than for impulse response. In other words, the first data point contributing to a particular output is multiplied by the coefficient associated with tap 0, and the last data point is multiplied by the coefficient associated with tap 3 or tap 6 (depending on whether it is 4-tap or 7-tap mode). The normal raster-scan order is used where the upper-left corner gets the (0, 0) coordinate. Pixel 0 is the left-most column of pixels for horizontal resizing, and the top-most row of pixels for vertical resizing. [Figure 1-34](#) shows an example of the alignment of input pixels to tap coefficients using a simple 1:1 resize case (4-tap mode). In this example, only one phase output is necessary.

[Figure 1-34](#) shows the alignment of input pixels to tap coefficients.

**Figure 1-34. Alignment of Input Pixels to Tap Coefficients**

camisp-116

Figure 1-34 also shows how the first output is computed when all taps are aligned with input pixels. To compute the last several pixels in each line/column, the filter requires more input pixels than the following equation calculates:

$$\text{input size} = \text{output size} \times \text{RSZ} / 256$$

In the former example, where the input size is X and the output size is Y, three extra input pixels are required to generate the correct number of output pixels:

$$X = Y \times 256 / 256 + 3 \text{ (to account for the extra pixels required for filtering)}$$

The input size calculation depends on the starting phase and rounding issues in the algorithm. Table 1-25 lists the input size calculations derived from the algorithm description in Section 1.4.5.2.5. The input width and height parameters must be programmed strictly according to these equations; otherwise, incorrect hardware operation may occur.

**Table 1-25. Input Size Calculations**

	8-Phase, 4-Tap Mode	4-Phase, 7-Tap Mode
<b>RSZ_IN_SIZE[12:0] HORZ</b>	$(32 \times \text{sph} + (\text{ow} - 1) \times \text{hrsz} + 16) \gg 8 + 7$	$(64 \times \text{sph} + (\text{ow} - 1) \times \text{hrsz} + 32) \gg 8 + 7$
<b>RSZ_IN_SIZE[28:16] VERT</b>	$(32 \times \text{spv} + (\text{oh} - 1) \times \text{vrsz} + 16) \gg 8 + 4$	$(64 \times \text{spv} + (\text{oh} - 1) \times \text{vrsz} + 32) \gg 8 + 7$

Where:

sph = Start phase horizontal (RSZ\_CNT [22:20] HSTPH)

spv = Start phase vertical (RSZ\_CNT [25:23] VSTPH)

ow = Output width (RSZ\_OUT\_SIZE [11:0] HORZ + extra)

oh = Output height (RSZ\_OUT\_SIZE [27:16] VERT)

hrsz = Horizontal resize value (RSZ\_CNT [9:0] HRSZ + 1)

vrsz = Vertical resize value (RSZ\_CNT [19:10] VRSZ + 1)

extra = 0 when RSZ\_YENH [17:16] ALGO = 0 (edge enhancement disabled)

extra = 4 when RSZ\_YENH [17:16] ALGO != 0 (edge enhancement enabled)

The horizontal and vertical starting phases can be programmed in the RSZ\_CNT [22:20] HSTPH and RSZ\_CNT [25:23] VSTPH fields, respectively. The chrominance data can be resized using bilinear interpolation or the same algorithm as the luminance data (RSZ\_CNT [29] CBILIN). For more information about how these fields are used in the algorithm, see [Section 1.4.5.2.5, Resampling Algorithm](#).

### 1.4.5.2.5 Resampling Algorithm

The resizer module uses the same resampling algorithm for the horizontal and vertical directions. For the rest of this section, the horizontal direction is used in describing the resampling algorithm. The algorithm is described first for the 4-tap/8-phase mode, then for the 7-tap/4-phase mode.

[Section 1.4.5.2.5.1](#) and [Section 1.4.5.2.5.2](#) explain the generic algorithm without detailing the differences between color components. [Section 1.4.5.2.5.3](#) describes how interleaved chroma are processed when input is YUV422.

#### 1.4.5.2.5.1 4-Tap/8-Phase Mode

In the 4-tap/8-phase mode, the coefficients for each of the 8 phases may be set to interpolate 8 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 56 input-pixel precision is incremented by the RSZ\_CNT [9:0] HRSZ +1 value. A coarse-input pointer with 1/8 input-pixel precision (corresponds to one of the 8 phases) is calculated by rounding the fine-input pointer to the nearest 1/8 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate four input pixels. [Figure 1-35](#) shows a pseudo-code description of the resizer algorithm in the 4-tap/8-phase mode.

**Figure 1-35. Pseudo-Code Description of the Resizer Algorithm in the 4-Tap/8-Phase Mode**

camisp-064

- The starting input pixel location (in whole pixels) (see [Section 1.4.5.2.3, Input and Output Interfaces](#)) and the starting phase (in 1/8 pixel) (RSZ\_CNT [22:20] HSTPH) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256-pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output, based on the fine-input pointer.
- The coarse-input pointer is in 1/8 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256\* starting input pixel + 32\* starting phase - 256. The fine-input pointer defines the starting 1/8 pixel location covered by the filter waveform.
- For each output pixel:

```
Coarse-input pointer =          /* Rounded to the nearest phase */
(fine-input pointer + 16) >> 5

Pixel-input pointer =          /* Rounded up to a whole pixel, when already on an
(coarse-input pointer >> 3) + 1 integer pixel, go to next one to simplify coefficient
                                organization */

Coefficient phase =            /* 3 LSBs = phase */
(coarse-input pointer & 7)

Output = dot product of the 4 coefficients and the 4 inputs starting with pixel-input pointer
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma
```

```

fine-input pointer = fine-input pointer
+ (RSZ_CNT [9:0] HRSZ + 1)

/* distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1) / 256 = (RSZ_CNT
[9:0] HRSZ + 1) in = 56 precision */

```

- Same algorithm in the horizontal and vertical directions, except with separate initial pixel/phase values and separate RSZ values.

#### 1.4.5.2.5.2 7-Tap/4-Phase Mode

In the 7-tap/4-phase mode, the coefficients for each of the 4 phases may be set to interpolate 4 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/56 input-pixel precision is incremented by the RSZ\_CNT [9:0] HRSZ + 1 value. A coarse-input pointer with = input-pixel precision (corresponds to one of the 4 phases) is calculated by rounding the fine-input pointer to the nearest = pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate 7 input pixels. Figure 1-36 shows a pseudo-code description of the resizer algorithm in the 7-tap/4-phase mode.

**Figure 1-36. Pseudo-Code Description of the Resizer Algorithm in the 7-Tap/4-Phase Mode**

camisp-065

- The starting input-pixel location (in whole pixels) (see Section 1.4.5.2.3, *Input and Output Interfaces*) and the starting phase (in = pixel) (RSZ\_CNT [22:20] HSTPH) are programmed through the resizer registers.
- A fine-input pointer is maintained in 56 pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output based on the fine-input pointer.
- The coarse-input pointer is in = pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256 \* starting input pixel + 64 \* starting phase - 256. The fine-input pointer defines the starting = pixel location covered by the filter waveform.
- For each output pixel:

```

Coarse-input pointer =                /* Round to the nearest phase */
(fine-input pointer + 32) >> 6

Pixel-input pointer =                /* Round up to a whole pixel; when already on an
(coarse-input pointer >> 2) + 1      integer pixel, go to next one to simplify coefficient
                                   organization */

Coefficient phase =                  /* 2 LSBs = phase */
(coarse-input pointer & 3)

Output = Dot product of the 7 coefficients and the 7 inputs starting with the pixel-input
pointer

Clip output to 8-bit unsigned for luma, 8-bit signed for chroma

/* It is acceptable to require the 8th coefficients to be filled with zeros by firmware so that 8
coefficients and 8 inputs, the last input being don't care value, are multiply-added */

Fine-input pointer = Fine input pointer + (RSZ_CNT [9:0] HRSZ + 1)

```

```
/* Distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1)/256 =
(RSZ_CNT [9:0] HRSZ + 1) in 56 precision */
```

- Same algorithm in both the horizontal and vertical directions, but with separate initial pixel/phase values and separate RSZ values.

---

**Note:** The pixel-input pointer, pip, in the algorithm description, points to pixels, not bytes or shorts in the memory. The fine-input pointer, fip, points to a =56 resolution sub-pixel position. The coarse-input point, cip, points to a 1/8 or 1/4 resolution sub-pixel location, depending on the number of phases.

---

#### 1.4.5.2.5.3 Horizontal Resizing With Interleaved Chroma

Chroma inputs, Cb and Cr, are 8-bit unsigned values that represent 128-biased 8-bit signed values (the signed chroma are called U and V instead of Cb and Cr). During the resizing computation, the chroma values have the 128 bias subtracted to convert to the 8-bit signed format. After vertical resizing, the 128 bias is added back to convert back to 8-bit unsigned format.

Chroma components, which are 2:1 horizontally downsampled with respect to luma, have two methods of horizontal resizing processing: filtering with luma, and bilinear interpolation.

The horizontal resizing with interleaved chroma option can be selected in the RSZ\_CNT [29] CBILIN field independently of the RSZ\_CNT [22:20] HSTPH parameters. However, filtering with luma is only intended for downsampling, and bilinear interpolation is only intended for upsampling.

For horizontal resizing of Y/Cb/Cr in a combined filtering flow, the algorithm is modified as shown in the following algorithm descriptions:

##### Filter Chroma With Luma (4-Tap/8-Phase Mode):

```
For (l=0; l<output_width; l++) { /* output width depends of input width and resizing factors*/
    Coarse-input pointer = (fine-input pointer + 16) >> 5    /* Round to nearest phase */
    Pixel-input pointer = (coarse-input pointer >> 3) + 1    /* Round up to a whole pixel */
    Coefficient phase = pixel-input pointer & 7                /* 3 LSB = phase */

    if (l & 1 == 0) { /* even output pixel, generate YCbCr */
        Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
        Cbout = dot product of the 4 coefficients and the 4 upsampled Cb inputs starting with
        pixel-input pointer
        Crout = dot product of the 4 coefficients and the 4 upsampled Cr inputs starting with
        pixel-input pointer
        Clip outputs to 8-bit unsigned for luma, 8-bit
        signed for chroma
    }
    Else { /* odd output pixel, generate Y only */
        Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
        Clip output to 8-bit unsigned
    }
    Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
}
```

### Filter Chroma With Luma (7-Tap/4-Phase Mode):

```

For (l=0; i<output_width; l++) { /* output width depends of input width and resizing factors*/
    Coarse-input pointer = (fine-input pointer + 32) >> 5 /* Round to nearest phase */
    Pixel-input pointer = (coarse-input pointer >> 2) + 1 /* Round up to a whole pixel */
    Coefficient phase = pixel-input pointer & 3 /* 2 LSB = phase */

    if (l & 1 == 0) { /* Even output pixel, generate YCbCr */
        Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
        Cbout = dot product of the 7 coefficients and the 7 upsampled Cb inputs starting with
        pixel-input pointer
        Crout = dot product of the 7 coefficients and the 7 upsampled Cr inputs starting with
        pixel-input pointer
        Clip outputs to 8-bit unsigned for luma, 8-bit
        signed for chroma
    }
    Else { /* Odd output pixel, generate Y only */
        Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
        Clip output to 8-bit unsigned
    }

    Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
}

```

---

**Note:** The chroma input values are internally replicated to realize 1:2 upsampling to line up with luma input values. Only required chroma outputs are computed; they correspond to even luma outputs.

---

### Bilinear Interpolation (4-Tap or 7-Tap):

For the bilinear interpolation flow of chroma horizontal resizing, the algorithm is adapted as follows. For the bilinear interpolation option, it is not necessary to replicate chroma samples.

```

For (l=0; i<output_width; l++) {
    if (l & 1 == 0) { /* even output pixel, generate YCbCr */
        Coarse-input pointer = ... /*Calculation issued from 4 taps or 7
        taps*/
        Pixel-input pointer = ... /*Calculation issued from 4 taps or 7 taps*/
        Yout = dot product of ... /*Calculation issued from 4 taps or 7
        taps*/
        C_fine_input_pointer = fine_input_pointer + 128*ntaps /* Points to center of filter
        kernel */
        Cidx = C_fine_input_pointer >> 9 /* Truncate to even pixel
        grid to find left value */
        Cbin[0] = Cb[Cidx]
    }
}

```

```

    Cbin[1] = Cb[Cidx + 1]
    Crin[0] = Cr[Cidx]
    Crin[1] = Cr[Cidx + 1]
    frac = C_fine_input_pointer & 511 /* 9-bit fraction */
    Cbout = ((512 - frac) * Cbin[0] + frac * Cbin[1] + 256) >> 9
    Crout = ((512 - frac) * Crin[0] + frac * Crin[1] + 256) >> 9
    Clip outputs to 8-bit unsigned for luma, 8-bit signed for chroma
    Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}

Else { /* odd output pixel, generate Y only */
    ...
}
}

```

In the former algorithm, fixed-point arithmetic is used. The variable *frac* is an unsigned integer representing the fraction *f*. Thus, 1- *f* becomes 512 - *frac*. After the sum of products, 256, representing 0.5 real-numbers, is added to the sum, and then the sum is right-shifted by 9 bits to get back to the integer chroma representation.

In both algorithm options, the chroma outputs computed are interleaved with luma values to generate the YCbYCr output format (or the alternate format specified in RSZ\_CNT [26] YCPOS).

In the vertical resizing stage, the two chroma planes are processed interleaved as one separate image. Because there is no resolution issue vertically, and no horizontal dependency in vertical resizing, the vertical scheme is consistent with conventional processing, and is not analyzed here.

#### 1.4.5.2.5.4 Algorithm Functionality

Table 1-26 is an example of 1:2:56 (hrsz = 100) horizontal resizing that illustrates the address calculation and chroma processing in 4:2:2 format (4-tap 8-phase mode). The starting pixel and phase are assumed to be zero.

**Table 1-26. Processing Example for 1:2:56 Horizontal Resize**

Output	Y0	Cb0	Cr0	Y1	Y2	Cb2	Cr2	Y3	Y4	Cb4	Cr4	Y5
fip (+= hrsz)		-256		-156		-56		44		144		244
cip (= (fip+16)>>5)		-8		-5		-2		1		5		8
pip (= (cip>>3) + 1)		0		0		0		1		1		2
coef ph (= cip & 7)		0		3		6		1		5		0
Inputs needed (chroma filtered like luma)	Y0	Cb0	Cr0	Y0	Y0	Cb0	Cr0	Y1	Y1	Cb0	Cr0	Y2
	Y1	Cb2	Cr0	Y1	Y1	Cb0	Cr0	Y2	Y2	Cb2	Cr2	Y3
	Y2	Cb2	Cr2	Y2	Y2	Cb2	Cr2	Y3	Y3	Cb2	Cr2	Y4
	Y3	Cb2	Cr2	Y3	Y3	Cb2	Cr2	Y4	Y4	Cb4	Cr4	Y5
Cfip (= fip+512)		256				488				720		
Cidx (= Cfip >> 9)		0				0				1		
Inputs needed for chroma bilinear interpolation		Cb0	Cr0			Cb0	Cr0			Cb2	Cr2	
		Cb2	Cr2			Cb2	Cr2			Cb4	Cr4	

Note the distinction between using {Cb0, Cb0, Cb2, Cb2} and {Cb0, Cb2, Cb2, Cb4} as input to the filter. The 4 filter taps are applied in order, so with the different chroma component repetition, the result is different (even when the coefficient phase is the same).

The Cidx of the chroma bilinear interpolation flow points to the chroma sample in linear array order, so Cidx = 1 means we Cb2 and Cb4 are being grabbed.

#### 1.4.5.2.6 Luma Edge Enhancement

Edge enhancement can be applied to the horizontally resized luminance component before the output of the horizontal stage is sent to the line memories and the vertical stage. The RSZ\_YENH [17:16] ALGO parameter can be set to disable edge enhancement, or to select a 3-tap or a 5-tap horizontal high-pass filter (HPF) for luminance enhancement. The edge enhancement algorithm is as follows:

If edge enhancement is selected, the two left-most and two right-most pixels in each line are not outputted to the line memories and the vertical stage. The RSZ\_OUT\_SIZE [11:0] HORZ register is the final output width, up to 1280 pixels when vertical 4-tap mode is used, and up to 640 pixels when vertical 7-tap mode is used. When edge enhancement is enabled, the horizontal resizer output width used to calculate the required input width must be RSZ\_OUT\_SIZE [11:0] HORZ + 4.

RSZ\_YENH [7:0] CORE is in U8Q0. RSZ\_YENH [11:8] SLOP is in U4Q4. RSZ\_YENH [15:12] GAIN is in U4Q4.

### 1.4.6 Statistics Collection Modules (SCMs)

The statistics-collection modules are the H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems.

#### 1.4.6.1 Statistics Collection: H3A

##### 1.4.6.1.1 Features

The H3A module supports control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- **Autofocus engine (AF):**  
The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a two-dimensional block of data referred to as a paxel. The AF engine supports the following features:
  - Peak mode in a paxel (a Paxel is defined as a two dimensional block of pixels): Accumulation of the maximum focus value of each line in a paxel.
  - Accumulation mode
  - Accumulation/Sum Mode (instead of Peak mode). Accumulation of focus value in a paxel.
  - Up to 36 paxels/windows in the horizontal direction and up to 128 paxels/windows in the vertical direction
  - Programmable width and height for the paxel/window
  - Programmable red, green, and blue position within a 2x2 matrix
  - Separate horizontal start for paxel and filtering
  - Programmable vertical line increments within a paxel
  - Parallel IIR filters configured in a dual-biquad configuration with individual coefficients (2 filters with 11 coefficients each)
- **Auto exposure and auto white balance engine (AE/AWB)**  
The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the two-dimensional block of data is referred to as a window.

Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

- Accumulation of clipped pixels along with all nonsaturated pixels
- Up to 36 horizontal windows/paxel and up to 128 vertical windows/paxel
- Separate vertical start coordination and height for a black row of paxels different from the remaining color paxels
- Programmable horizontal and vertical sampling points in a window

#### 1.4.6.1.2 Autofocus Engine

The autofocus engine works by extracting each red, green, and blue pixel from the video stream and subtracting a fixed offset from the pixel value (128 when A-Law is enabled or 512 when A-Law is disabled). The offset value is then passed through two IIR filters, and the absolute values of the filter outputs are the focus values (FV). For each paxel, the pixel values and the two focus value outputs are accumulated for each color and sent to memory. The following sections describe this process in more detail.

Only RAW10 data is supported by the autofocus function. In some cases, RAW8 or RAW12 data can be converted to RAW10 using the data-lane shifter.

#### 1.4.6.1.3 AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows and further subsampling each window into 2x2 blocks. Then, for each subsampled 2x2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2x2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

### 1.4.6.2 Statistics Collection: Histogram

#### 1.4.6.2.1 Features

The histogram accepts RAW image/video data from either the video-port interface of the CCDC or from memory, performs a color-separate gain on each pixel (white/channel balance), and bins the pixels according to the amplitude, color, and region specified through the CCDC register settings. It can support either 3 or 4 colors (Foveon or Bayer), and up to 4 regions, simultaneously. [Figure 1-37](#) shows the processing of the histogram module.

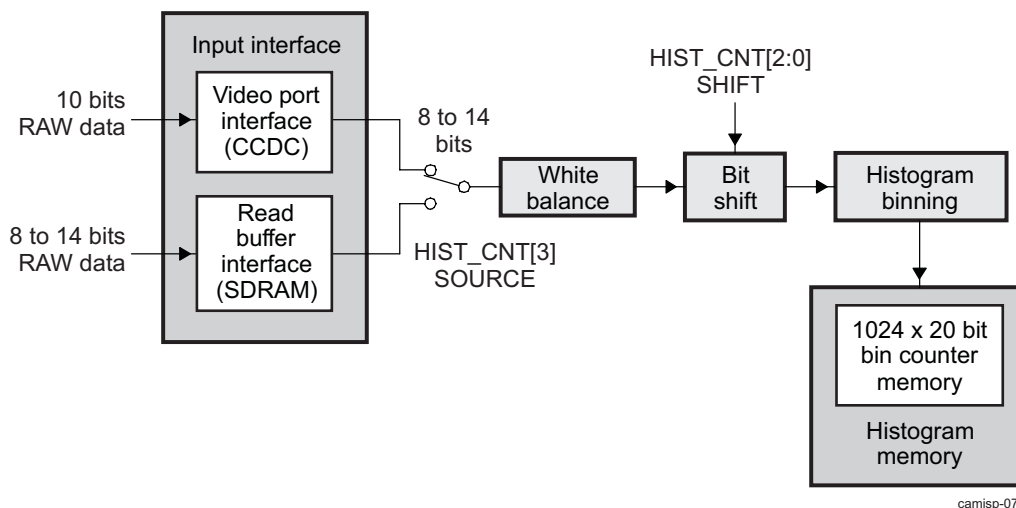

The histogram module is typically used with 3A metrics by the host processor to adjust various parameters for processing image data. The following features are supported:

- Flexible input: Input data can come from the RAW image sensor (through the CCDC module) or from memory.
- Color-separate gain: A digital gain per color component can be applied before histogram computation.
- Histogram computation: The module performs pixel binning of the incoming RAW image data. Each bin collects the number of pixels with values in a range. If no saturation occurs, the sum of the values in every bin is equal to the total number of pixels in the input image. The histogram computation can occur over one frame or be accumulated over multiple frames. The computation occurs on rectangular regions. A histogram is computed for each color component in the image:
  - The RAW image data dynamic can be up to 10 bits (pixel values in the range 0 to 1023).
  - Range: Each bin covers a pixel range. Each bin can cover a maximum of 128 pixel values.
  - Programmable regions: There can be up to 4 regions. The region positions and horizontal and vertical sizes are programmable. When regions overlap, pixels from the overlapped area are accumulated into the highest-priority region only; region0 has the highest priority and region3 the lowest priority.
  - Programmable number of bins: There can be 32, 64, 128, or 256 bins per color and per region. The number of bins depends on the number of regions, because histogram memory size is fixed.

- Color components: A histogram is computed for each color component in the RAW image. There are usually 3 color components in Foveon image sensors and 4 color components in Bayer image sensors.
- Saturation: If the pixel count exceeds  $2^{20}-1$ , the pixel count is saturated.
- Memory clear: The histogram memory is cleared automatically when it is read.
- Output: The histogram result is stored in a local RAM read by a system initiator, typically the system DMA, to be written to memory.

#### 1.4.6.2.2 Block Diagram

**Figure 1-37. Histogram Process**

camisp-073

#### 1.4.6.2.3 Input Interface

The histogram receives RAW image/video data from the video port interface through the CCDC (which is interfaced to an external sensor) or from the read buffer interface through memory (HIST\_CNT [3] SOURCE).

The input data is 10 bits wide if the source is the video-port interface. When the input source is from memory, data-bit width can range from 8 to 14 bits. If the input data is 8 bits packed (memory contains two 8-bit pixels for every 16 bits), the HIST\_CNT [8] DATSIZ bit must be set. If memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared.

Likewise, if memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared. The input memory address (HIST\_RADD) and line-offset (HIST\_RADD\_OFF) registers are used to specify the location of the input frame in memory. Both of these registers should be aligned on 32-byte boundaries.

The frame-input width and height are configured using the HIST\_H\_V\_INFO [29:16] HSIZE and HIST\_H\_V\_INFO [13:0] VSIZE register fields, respectively.

The histogram module supports 4-color Bayer and 3-color Foveon color patterns. The HIST\_CNT [6] CFA field is used to select the color pattern of the input data (Bayer or Foveon).

#### 1.4.6.2.4 White Balance

A white-balance gain can be separately applied to each color channel by programming the fields in the HIST\_WB\_GAIN register. [Table 1-27](#) indicates which pixel index in the color pattern corresponds to each field in the WB\_GAIN register.

**Figure 1-38. Color Pattern Indexes**

Bayer	
0	1
2	3

camisp-074

**Table 1-27. White Balance Field-to-Pattern Assignments**

HIST_WB_GAIN fields	Bayer
WG00	0
WG01	1
WG02	2
WG03	3

Each gain constant is 8 bits wide with 5 bits of decimal precision (U8Q5).

#### 1.4.6.2.5 Histogram Binning

The histogram bins the input data by amplitude, color, and region (see [Figure 1-39](#)). Each bin is a counter, counting the number of pixels of a color in the range associated with the bin. The number of bins can be programmed to 32, 64, 128, or 256 bins in the HIST\_CNT [5:4] BINS field. However, due to limited histogram memory size (1024 words), the number of bins (times 4 colors) limits the number of regions that can be active, as shown in [Table 1-28](#).

**Table 1-28. Regions and Bins for Histogram**

Number of Bins	Number of Regions Allowed
256	1
128	2"
64	4
32	4

As indicated by [Table 1-28](#), up to four overlapping regions can be designated within the frame. Each region is defined by the horizontal starting (HIST\_Rn\_HORZ [29:16] HSTART) and ending (HIST\_Rn\_HORZ [13:0] HEND) pixels, and the vertical starting (HIST\_Rn\_VERT [29:16] VSTART) and ending (HIST\_Rn\_VERT [13:0] VEND) lines (where n is the region number 0...3).

#### 1.4.6.2.5.1 Region Priority

Up to four regions can be active at any time, but a pixel is binned into only one region. The priority is Region 0 > Region 1 > Region 2 > Region 3. For example, the yellow pixel in [Figure 1-39](#) is binned only for Region 0, although it is present in all four regions.

**Figure 1-39. Region Priority**

### 1.4.7 Central-Resource Shared Buffer Logic (SBL)

The central-resource SBL receives data read and write requests from the CCDC, preview, H3A, histogram, and resizer modules. It arbitrates between requestors and constructs bursts to transfer data to and from memory.

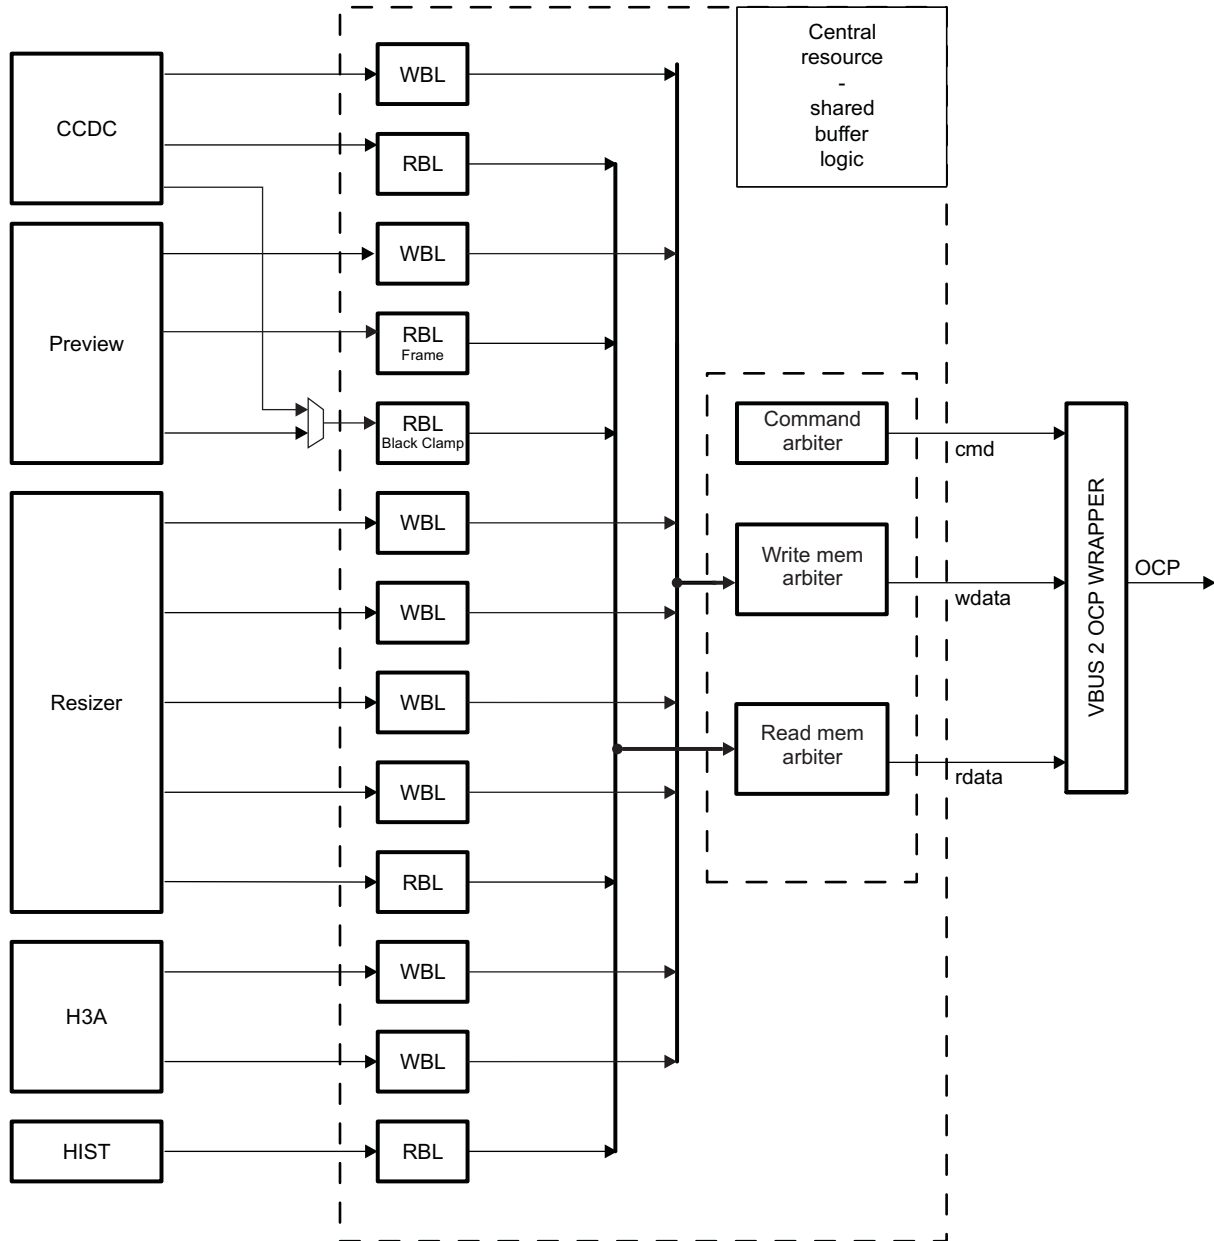

The central-resource SBL performs the following functions:

- Interface to the CCDC module:
  - Collects output data from the CCDC in the write buffer (1 port)
  - Transfers faulty-pixel table data to the CCDC from the read buffer (2 ports)
  - Transfer lens-shading compensation to the CCDC engine from the read buffer. This port is shared with PREVIEW module dark frame subtract port.
- Interface to the preview module:
  - Collects output data from the preview engine in the write buffer (1 port)
  - Transfer input data to the PREVIEW engine from the read buffer (1 ports).
  - Transfer dark frame subtract data to the PREVIEW engine from the read buffer . This port is shared with CCDC lens-shading compensation read port.
- Interface to the H3A module:
  - Collects output data from the H3A in the write buffer (2 ports)
- Interface to the histogram module:
  - Transfers input data to the histogram from the read buffer (1 port)
- Interface to the resizer module:
  - Collects output data from the resizer in the write buffer (4 ports)
  - Transfers input data to the resizer from the read buffer (1 port)
- Requests arbitration between the different initiators. Based on fixed priorities.
- Performs throttle memory read requests for preview, resizer, and histogram to limit bandwidth in memory-to-memory operations

### 1.4.7.1 Block Diagram

Figure 1-40 shows the central-resource SBL. It comprises WBL and RBL blocks, read and write buffers, and arbitration logic. The VBUSM data-width to the memory is 64 bits.

Figure 1-40. Central-Resource SBL Block Diagram

camisp-078

### 1.4.7.2 Functional Operations

#### 1.4.7.2.1 Parameters

Table 1-29 summarizes the central-resource SBL parameters. Those parameters are fixed at design time and cannot be changed by users. The functional operations of the central-resource SBL are based on a fixed data size of 256 bytes called a data unit (DU). P0 has the highest priority and P14 has the lowest priority.

**Table 1-29. Central Resource SBL Fixed Parameters**

Port	Port Direction	Port Priority	Buffer Size Bytes	Description
CCDC	WRITE	P4	1024 = 4DUs	CCDC output port
	READ	P1	512 = 2DUs	CCDC fault pixel correction input port
PREVIEW	WRITE	P9	1024 = 4DUs	PREVIEW output port
	READ	P13	1024 = 4DUs	PREVIEW input port
	READ	P0	1024 = 4DUs	PREVIEW dark-frame input port CCDC lens-shading compensation input port
RESIZER	WRITE	P5	1024 = 4DUs	RESIZER output line 1 port
	WRITE	P6	1024 = 4DUs	RESIZER output line 2 port
	WRITE	P7	1024 = 4DUs	RESIZER output line 3 port
	WRITE	P8	1024 = 4DUs	RESIZER output line 4 port
	READ	P12	1024 = 4DUs	RESIZER input port
H3A	WRITE	P10	512 = 2DUs	H3A output - AF port
	WRITE	P11	512 = 2DUs	H3A output - AE/AWB port
HIST	READ	P14	512 = 2DUs	HIST input port

#### 1.4.7.2.2 Write-Buffer Logic (WBL) and Write Buffer

The central-resource SBL uses multiple WBL blocks to interface between the modules' write ports and the write-buffer memory.

- One WBL is instantiated for each module write port.
- Each WBL collects the module's write port output data and transfers the data to the write-buffer memory. Arbitration occurs between the WBL blocks to access the write-buffer memory.
- Each WBL is responsible for tracking all corresponding DUs in the write-buffer memory. There can be 2 or 4 DUs in the write buffer associated with a WBL.
- A WBL generates a command to memory when:
  - The write data crosses a DU boundary. At this point, the module starts filling a new DU. Also, the WBL generates a command to transfer the previous DU to memory.
  - An end-of-frame occurs. The DU (even if not full) is transferred to memory, and a command is issued.
  - An end-of-line occurs. The DU (even if not full) is transferred to the memory, and a command is issued.

#### 1.4.7.2.3 Read Buffer Logic (RBL) and Read Buffer

The central-resource SBL uses multiple RBL blocks to interface between the modules' read ports and the read-buffer memory.

- One RBL is instantiated for each module read port.
- Each RBL is responsible for accepting input data from the read-buffer memory and for sending the input data to the read port of the corresponding module.
- Each RBL is responsible for tracking all corresponding DUs in the read-buffer memory. There can be 2 or 4 DUs in the read buffer associated with a RBL.
- Unlike the WBL, the RBL is not responsible for issuing the commands to memory; each individual module is responsible for doing this.

Two read ports are shared:

- Between the PREVIEW module dark frame and the CCDC lens-shading compensation input

They can only be used by one module at a given time because there's no arbitration mechanism. Software is responsible of enabling only one of the 2 possible features attached to a port and to select the correct multiplexer configuration using the ISP\_CTRL [27] SBL\_SHARED\_RPORTA and ISP\_CTRL [28] SBL\_SHARED\_RPORTB registers.

#### 1.4.7.2.4 Arbitration

The central-resource SBL arbitrates between module requests, based on fixed priorities. Read and write requests are arbitrated independently.

A total of 8 commands can be active at a time. When a new slot opens, the highest-priority transfer enters the command queue.

RBLs/WBLs are ensured access to the read/write buffer memories at least once every other cycle.

---

**Note:** The hardware uses burst. All bursts are precise; the total number of transfers in the burst is known at the start of the burst. All writes are posted.

---

#### 1.4.7.3 Memories

The central-resource shared-buffer module has three memories:

- READ BUFFER: Shared by all modules.
- WRITE BUFFER 0: Used only by the resizer module.
- WRITE BUFFER 1: Shared by all modules except RESIZER.

#### 1.4.7.4 Debug Registers

Some registers are available for debugging data transfers between a module and external memory. The read-only debug registers are divided into two categories:

- 8 global request registers to capture information about any of the 52 module request registers at a given time. Each register provides information about one DU. The number 16 corresponds to the maximum number of outstanding requests, according to the protocol. Each global request register provides the following information:
  - Individual module register command number. For modules with 2 individual requestors, this field displays either 0 or 1. For modules with 4 individual requestors, this field displays 0, 1, 2, or 3.
  - Source or destination module
  - Data-flow direction
  - Valid bit
- 52 individual module request registers (read or write information). Each register provides information about one DU. The number of request registers assigned (2 or 4) depends on memory bandwidth requirements; modules with lower requirements are assigned 2 request registers, while modules with higher bandwidths are assigned 4 request registers.

**Table 1-30. Central Resource SBL Number of Request Registers**

Port	RD/WR	Nb Request Registers	Description
CCDC	WRITE	4 WR request registers	CCDC output
	READ	2 RD request registers	CCDC fault pixel correction input
PREVIEW	WRITE	4 WR request registers	PREVIEW output
	READ	4 RD request registers	PREVIEW input
	READ	4 RD request registers	PREVIEW dark-frame input
RESIZER	WRITE	4 WR request registers	RESIZER output line 1
	WRITE	4 WR request registers	RESIZER output line 2
	WRITE	4 WR request registers	RESIZER output line 3

**Table 1-30. Central Resource SBL Number of Request Registers (continued)**

Port	RD/WR	Nb Request Registers	Description
	WRITE	4 WR request registers	RESIZER output line 4
	READ	4 RD request registers	RESIZER input port
H3A	WRITE	2 WR request registers	H3A output - AF port
	WRITE	2 WR request registers	H3A output - AE/AWB port
HIST	READ	2 RD request registers	HIST input

Each write-request register provides the following information:

- Current byte count: Number of bytes in the block of data for this command, up to 256 bytes
- Data ready: Block of data confirmed by the module
- Data sent: Data sent to the destination and waiting for status
- Upper 20 bits of the address

Each read-request register provides the following information:

- Valid: Read requested from the module
- Waiting for data: Command accepted from the source
- Data available: Data received from the source and can be read by the module
- Byte count requested: Up to 256 bytes
- Upper 20 bits of the address

### 1.4.8 Circular Buffer (CBUFF)

The circular buffer maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

---

**Note:** Addresses can be further translated by the MMU.

---

#### 1.4.8.1 Feature List

The features are listed below:

- 2 independent circular buffers (CBUFF0 and CBUFF1)
- Linear address space (virtual) mapped into a circular space (physical)
- Fully transparent for accesses out of the configured virtual space
- Maximum physical buffer size of 16x16M bytes:
  - Physical space is composed by 2,4,8 or 16 windows
  - Maximum allowed window size is 16M bytes
- Support for multi line write patterns
  - Used together with the resizer in upscale mode. Each buffer must contain at least ceil (vertical zoom factor) images lines
- Support of 2D addressing modes
- Strong error detection mechanisms
- Buffer addresses are 64 bit aligned but window fill level managing is byte accurate
- Read and write accesses are supported

#### 1.4.8.2 Interrupts

All events generated (see [Table 1-11](#) for details) by the circular buffer are merged into a single event at camera ISP level. This event can be mapped to MPU SS by enabling the ISP\_IRQ0ENABLE [21] CBUFF\_IRQ bit or to IVA2.2 by enabling the ISP\_IRQ1ENABLE [21] CBUFF\_IRQ bit.

### 1.4.8.3 Functional Description

The circular buffer module (CBUFF) maps a virtual address space to a physical space called circular buffer. The CBUFF module can handle up to 2 independent circular buffers CBUFF0 and CBUFF1.

This section gives an overview of typical utilizations of the module.

#### 1.4.8.3.1 Window Management

This section explains the internal address remapping and windows management algorithm. Internally the module maintains some variables in addition to the configuration registers.

The module manages 2 circular buffers in parallel. Those are called CBUFF0 and CBUFF1.

**Table 1-31. Internal Variables**

Quantity	Description
CWx	Current window index for buffer x (x=0,1). Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS [11:8] CW register.
NWx	Next window index for buffer x (x=0,1). Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS [19:16] NW register.
CPUWx	Window in the physical buffer that can be accessed by the CPU. Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS [3:0] CPUW register.
FCOx	Start address, in the virtual space, of the current window. This is an internal quantity that cannot be accessed by SW.
OFFSETy	This is an internal quantity that cannot be accessed by SW. y=0: Address offset used when the current window of buffer 0 is accessed y=1: Address offset used when the next window of buffer 0 is accessed y=2: Address offset used when the current window of buffer 1 is accessed y=3: Address offset used when the next window of buffer 1 is accessed
LEVELy	This is an internal quantity that cannot be accessed by SW. y=0: Amount of data, in bytes, read or written in the current window of buffer 0 y=1: Amount of data, in bytes, read or written in the next window of buffer 0 y=2: Amount of data, in bytes, read or written in the current window of buffer 1 y=3: Amount of data, in bytes, read or written in the next window of buffer 1

#### 1.4.8.3.1.1 Startup

The status of a circular buffer (CBUFF0 or CBUFF1) is reset when it is disabled. This does not affect the configuration registers or the CBUFF\_IRQSTATUS register. [Table 1-32](#) shows the internal state after reset.

**Table 1-32. Internal State After Reset**

Quantity	Description
CWx	0
NWx	1
CPUWx	0
FCOx	CBUFFx_START
OFFSET0	0
OFFSET1	0
OFFSET2,3	0
LEVELy	0

### 1.4.8.3.1.2 Access Identification

For each access to the virtual space the CBUFF module first checks the address (ADDR) to classify the transaction into one of the following categories listed in [Table 1-33](#).

**Table 1-33. Address Identification**

ID	Label	Condition
0	CW_CBUFF0	CBUFFx_CTRL[0] ENABLE=1 and ADDR>=FCO0 and ADDRFCO0 + CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 0)
1	NW_CBUFF0	CBUFFx_CTRL[0] ENABLE=1 (x = 0) and ADDR>=FCO0 + CBUFFx_WINDOWSIZE and ADDRFCO0 + 2*CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 0)
2	CW_CBUFF1	CBUFFx_CTRL[0] ENABLE=1 and ADDR>=FCO1 and ADDRFCO1 + CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 1)
3	NW_CBUFF1	CBUFFx_CTRL[0] ENABLE=1 and ADDR>=FCO1 + CBUFFx_WINDOWSIZE and ADDRFCO1 + 2*CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 1)
4	ERR_CBUFF0	CBUFFx_CTRL[0] ENABLE=1 and ADDR>= CBUFFx_START and ADDR= CBUFFx_END (x = 0)
5	ERR_CBUFF1	CBUFFx_CTRL[0] ENABLE=1 and ADDR>= CBUFFx_START and ADDR= CBUFFx_END (x = 1)
6	TRANSPARENT	Always true

Lower IDs correspond to higher priorities in case multiple conditions are true. For example when the current virtual window of the circular buffer 0 is accessed, at least the tests for categories CW\_CBUFF0 and ERR\_CBUFF0 are true. The final category is CW\_CBUFF0 because it has a higher priority.

Further processing depends on the category:

- **TRANSPARENT:** Accesses flow through the module, without changing its internal state or any translation.
- **ERR\_CBUFF0 and ERR\_CBUFF1:** The module goes into error state for the concerned buffer (CBUFF0 or CBUFF1) and set the CBUFF\_IRQSTATUS[1] IRQ\_CBUFF0\_INVALID bit (or CBUFF\_IRQSTATUS[4] IRQ\_CBUFF1\_INVALID). When the module is in error state for CBUFFx, all accesses to that buffer are cancelled. In other words, any access that has an address between CBUFFx\_START and CBUFFx\_END (x = 0) is not transmitted to the interconnect. There are 2 ways to leave the error state
  - HW reset
  - Disable and re-enable the buffer (CBUFF0 or CBUFF1) in error state.
 Accesses outside of the virtual space from the circular buffer in error state are not affected.
- **CW\_CBUFF0, NW\_CBUFF0, CW\_CBUFF1 and NW\_CBUFF1:** The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the current mode (read or write). Otherwise an IRQ\_CBUFFx\_INVALID event is set and CBUFFx goes to the error state.

### 1.4.8.3.1.3 Address Translation

An offset is selected depending on the access category (check section [Section 1.4.8.3.1.1](#)) and the internal state of the accessed buffer. [Table 1-34](#) lists possible cases.

**Table 1-34. Address Translation**

Condition	Address Translation
CBUFFx_CTRL[0] ENABLE=1 and ADDR >= CBUFFx_START and ADDR = CBUFFx_END and CBUFF0 in error state (x = 0)	Access cancelled
CBUFFx_CTRL[0] ENABLE=1 and ADDR >= CBUFFx_START and ADDR = CBUFFx_END and CBUFF1 in error state (x = 1)	Access cancelled
Category = CW_CBUFF0	ADDROUT = ADDRIN-OFFSET0
Category = NW_CBUFF0	ADDROUT = ADDRIN-OFFSET1
Category = CW_CBUFF1	ADDROUT = ADDRIN-OFFSET2
Category = NW_CBUFF1	ADDROUT = ADDRIN-OFFSET3
Category = ERR_CBUFF0	Access cancelled
Category = ERR_CBUFF1	Access cancelled
Category = TRANSPARENT	ADDROUT = ADDRIN

#### 1.4.8.3.1.4 Window Fill Level

Each time an access is performed into an active window (CW\_CBUFF0, NW\_CBUFF0, CW\_CBUFF1 or NW\_CBUFF1) the window level is updated. The corresponding LEVELy is incremented according to the BYTEEN input of the interconnect port. All possible BYTEEN patterns are supported. [Table 1-35](#) shows some examples. The basic idea is to count the number of ones in the BYTEEN input.

**Table 1-35. Window Level Increment**

BYTEEN	LEVELy Increment	Comment
0x00	+0	No access
0x01	+1	8 bit access
0x02	+1	8 bit access
0x03	+2	16 bit access
...	...	...
0x07	+3	24 bit access
...	...	...
0x0F	+4	32 bit access
...	...	...
0xF0	+4	32 bit access
...	...	...
0xFF	+8	64 bit access

The window level is compared to CBUFFx\_THRESHOLD. As listed in [Table 1-36](#), the following situations may occur:

**Table 1-36. Window Level Comparison**

Condition	Description
LEVEL0 >= CBUFFx_THRESHOLD (x = 0)	Current window of buffer 0 full. Internal window indexes, levels and offsets are updated
LEVEL1 >= CBUFFx_THRESHOLD (x = 0)	Next window of buffer 0 full. An IRQ_CBUFF0_INVALID error event is set and CBUFF0 enters the error state
LEVEL2 >= CBUFFx_THRESHOLD (x = 1)	Current window of buffer 1 full.
LEVEL3 >= CBUFFx_THRESHOLD (x = 1)	Next window of buffer 1 full. An IRQ_CBUFF1_INVALID error event is set and CBUFF1 enters the error state

#### 1.4.8.3.1.5 Window Pointer and Offset Update

When the current window of a circular buffer (CBUFFx, x=0 or 1) is full:

- The "next window" becomes the "current window"
  - $CWx \leftarrow NW$
  - $LEVEL(2*x) \leftarrow LEVEL(2*x+1)$
  - $OFFSET(2*x) \leftarrow OFFSET(2*x+1)$
  - $FCOx \leftarrow FCOx + CBUFFx\_WINDOWSIZE$
- A new "next window" is opened. The update is done in a circular manner: the first window in the physical space is reused after the last one
  - $NW \leftarrow (NW+1) \text{ modulo } WC$
  - $LEVEL(2*x+1) \leftarrow 0$
  - When the "next window" is moved from the last buffer to the first:
    - $OFFSET(2*x+1) \leftarrow OFFSET(2*x+1) + WCx * CBUFFx\_WINDOWSIZE$

---

**Note:** WC is the window count defined by the CBUFFx\_CTRL[9:8] WCOUNT register.

---

#### 1.4.8.3.2 CPU Interaction

The CBUFF module sets an IRQ\_CBUFFx\_READY event to inform the CPU that it can access the CPUx window in the physical buffer. The CBUFF module cannot monitor CPU accesses to the physical buffer. The CPU must indicate when it has completed the processing of the CPUWx window by writing the CBUFFx\_CTRL[2] DONE bit. This increments the CPU window index CPUWx by one modulo the window count.

The behavior depends if read or write mode has been selected using the CBUFFx\_CTRL[1] RWMODE bit.

### 1.4.9 MMU Logic

#### 1.4.9.1 MMU Features

The camera ISP MMU contains a translation lookaside buffer (TLB) that holds translations and properties for current pages. This TLB can be managed statically through the configuration slave port, or by the internal hardware table-walking logic (TWL), which can autonomously traverse the page table on a TLB miss. The TWL can be enabled or disabled (MMU\_CNTL [2] TWLENABLE).

On a TLB miss, the initiator is stalled until a valid address translation is found. If no valid translation is found, a translation fault interrupt is generated to the processor. It is a nonrecoverable situation, which leads to the camera ISP being reset by the processor software.

The MMU provides up to 4G bytes of virtual memory.

#### 1.4.9.2 MMU Functional Description

For a detailed description of MMU, see the *Memory Management Units* chapter.

---

**Note:** In the camera ISP MMU, the endianness feature is available for write, but conversion for read is not possible.

---

## 1.5 Camera ISP Basic Programming Model

### 1.5.1 Programming the Timing CTRL Module

---

**Note:** All the following settings must be done before enabling the Timing control module.

---

#### 1.5.1.1 Timing Generator

The cam\_xclka clock frequency is set through the TCTRL\_CTRL [4:0] DIVA bit field. The cam\_xclkb clock frequency is set through the TCTRL\_CTRL [9:5] DIVB bit field. One can change the divisor values at any time.

For divisor values 0, 1, and 31, the divider is not enabled. For all other values:

- $\text{cam\_xclka} = \text{cam\_mclk} / \text{TCTRL\_CTRL [4:0] DIVA}$
- $\text{cam\_xclkb} = \text{cam\_mclk} / \text{TCTRL\_CTRL [9:5] DIVB}$

#### 1.5.1.2 Camera-Control Signal Generator

Enabling of the SHUTTER, PRESTROBE or STROBE signals generation and activates the counters:

- TCTRL\_CTRL [21] SHUTEN = 1
- TCTRL\_CTRL [22] PSTRBEN = 1
- TCTRL\_CTRL [23] STRBEN = 1

Two configurations apply:

- The control signals are based on the vertical synchronization information coming from the camera module or from the externally generated cam\_global\_reset signal.
- The control signals are based on the internally generated cam\_global\_reset.

##### 1.5.1.2.1 Vertical Synchro-Based Control-Signal Generation or Externally-Generated cam\_global\_reset

Before enabling the control-signal generation, the following registers must be set:

- Select the input that triggers the control signals. The trigger signal can come from the PARALLEL or the externally-generated cam\_global\_reset signal.
  - TCTRL\_CTRL [28:27] INSEL
- The signal must be set to INPUT:
  - TCTRL\_CTRL [31] GRESETDIR = 0x0
  - Writes to TCTRL\_CTRL [29] GRESETEN bit do not trigger the PRESTROBE, STROBE, and SHUTTER signals, and do not generate the cam\_global\_reset signal.
- The following bits are cleared automatically to 0 after the signal assertion:
  - TCTRL\_CTRL [21] SHUTEN
  - TCTRL\_CTRL [22] PSTRBEN
  - TCTRL\_CTRL [23] STRBEN
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam\_global\_reset signals. The signals can be active high or active low:
  - TCTRL\_CTRL [24] SHUTPOL
  - TCTRL\_CTRL [26] STRBPSTRBPOL
  - TCTRL\_CTRL [30] GRESETPOL
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
  - TCTRL\_CTRL [18:10] DIVC

The clock is set by  $\text{CNTCLK} = \text{cam\_mclk} / \text{TCTRL\_CTRL [18:10] DIVC}$ . The possible values are 0 to 511. Setting DIVC = 0 disables the CNTCLK clock generation.
- The frame counters are set with (possible values are 0 to 63 frames):

- TCTRL\_FRAME [5:0] SHUT
- TCTRL\_FRAME [11:6] PSTRB
- TCTRL\_FRAME [17:12] STRB

---

**Note:** If the value is zero, the Timing Control module does not delay any frame in input.

---

- The delay counters are set with:
  - TCTRL\_SHUT\_DELAY
  - TCTRL\_PSTRB\_DELAY
  - TCTRL\_STRB\_DELAY

The possible values are 0 to  $2^{25} - 1$  cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{25} - 1) \times 2.366 \text{ us} = 79 \text{ s}$  (TCTRL\_CTRL [18:10] DIVC = 511).
- The signal durations are set with:
  - TCTRL\_SHUT\_LENGTH
  - TCTRL\_PSTRB\_LENGTH
  - TCTRL\_STRB\_LENGTH

The possible values are 0 to  $2^{24} - 1$  cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{24} - 1) \times 2.366 \text{ us} = 39.69 \text{ s}$  (TCTRL\_CTRL [18:10] DIVC = 511).

#### 1.5.1.2.2 Internally-Generated cam\_global\_reset-Based Control-Signal Generation

Before enabling the cam\_global\_reset control-signal generation by writing TCTRL\_CTRL [29] GRESETEN = 1, the following registers must be set:

---

**Note:** Setting TCTRL\_CTRL [21] SHUTEN, TCTRL\_CTRL [22] PSTRBEN, TCTRL\_CTRL [23] STRBEN, and TCTRL\_CTRL [29] GRESETEN to 1 simultaneously leads to unpredictable behavior. The TCTRL\_CTRL [21] SHUTEN, TCTRL\_CTRL [22] PSTRBEN, TCTRL\_CTRL [23] STRBEN must be set before TCTRL\_CTRL [29] GRESETEN is enabled.

---

- The signal must be set to OUTPUT:
  - TCTRL\_CTRL [31] GRESETDIR = 0x1
  - Vertical synchronization events do not trigger the PRESTROBE, STROBE, and SHUTTER signals.
- The following bits are cleared automatically to 0 after the signal assertion:
  - TCTRL\_CTRL [21] SHUTEN
  - TCTRL\_CTRL [22] PSTRBEN
  - TCTRL\_CTRL [23] STRBEN
  - TCTRL\_CTRL [29] GRESETEN
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam\_global\_reset signals. The signals can be active high or active low:
  - TCTRL\_CTRL [24] SHUTPOL
  - TCTRL\_CTRL [26] STRBPSTRBPOL
  - TCTRL\_CTRL [30] GRESETPOL
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
  - TCTRL\_CTRL [18:10] DIVC

The clock is set by  $\text{CNTCLK} = \text{cam\_mclk} / \text{TCTRL\_CTRL [18:10] DIVC}$ . The possible values are 0 to 511. Setting DIVC = 0 disables the CNTCLK clock generation.
- The frame counters bit fields are ignored:
  - TCTRL\_FRAME [5:0] SHUT
  - TCTRL\_FRAME [11:6] PSTRB
  - TCTRL\_FRAME [17:12] STRB
- The delay counters are set with:
  - TCTRL\_SHUT\_DELAY

- TCTRL\_PSTRB\_DELAY
- TCTRL\_STRB\_DELAY

The possible values are 0 to 225 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(225 - 1) \times 2.366 \text{ us} = 79 \text{ s}$  (TCTRL\_CTRL [18:10] DIVC = 511).

- The signal durations are set with:

- TCTRL\_SHUT\_LENGTH
- TCTRL\_PSTRB\_LENGTH
- TCTRL\_STRB\_LENGTH

The possible values are 0 to 224 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(224 - 1) \times 2.366 \text{ us} = 39.69 \text{ s}$  (TCTRL\_CTRL [18:11] DIVC = 511).

- The cam\_global\_reset assertion time is set by TCTRL\_GRESET\_LENGTH. The possible values are 0 to 224 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(224 - 1) \times 2.366 \text{ us} = 39.69 \text{ s}$  (TCTRL\_CTRL [18:11] DIVC = 511).

## 1.5.2 Programming the CCDC

This section discusses issues related to the software control of the CCDC. It lists which registers are required to be programmed in different modes, and describes how to enable and disable the CCDC, how to check the status of the CCDC, the different register access types, and programming constraints.

### 1.5.2.1 CCDC Hardware Setup/Initialization

This section discusses the configuration of the CCDC required before image processing can begin.

#### 1.5.2.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the CCDC are reset to their reset values.

#### 1.5.2.1.2 Register Setup

Before enabling the CCDC, the hardware must be correctly configured through register writes. [Table 1-37](#) identifies the register parameters that must be programmed before enabling the CCDC.

**Table 1-37. CCDC Required Configuration Parameters**

Function	Configuration Required
External pin signal configuration	CCDC_SYN_MODE [0] VDHDOUT
	CCDC_SYN_MODE [16] VDHDEN
	CCDC_SYN_MODE [2] VDPOL
	CCDC_SYN_MODE [3] HDPOL
	CCDC_SYN_MODE [7] FLDMODE
	CCDC_SYN_MODE [1] FLDOUT
	CCDC_SYN_MODE [4] FLDPOL
	CCDC_SYN_MODE [5] EXWEN
	CCDC_SYN_MODE [6] DATAPOL
	CCDC_CFG [15] VDLC = 1
	ISP_CTRL [3:2] PAR_BRIDGE
	ISP_CTRL [7:6] SHIFT
	ISP_CTRL [4] PAR_CLK_POL
Input mode	CCDC_REC656IF [0] R656ON
	CCDC_SYN_MODE [13 :12] INPMOD
Color pattern	CCDC_COLPTN
Black compensation	CCDC_BLKCMP

**Table 1-37. CCDC Required Configuration Parameters (continued)**

Function	Configuration Required
Faulty-pixel correction	CCDC_FPC [15] FPCEN
Data-path configuration	CCDC_FMTCFG [15] VPEN CCDC_SYN_MODE [18] VP2SDR CCDC_SYN_MODE [17] WEN CCDC_SYN_MODE [19] SDR2RSZ
Lens-shading compensation	CCDC_LSC_CONFIG [0] ENABLE

Table 1-38 identifies additional configuration requirements depending on whether the corresponding condition is met.

Table 1-38 can be read as: if (**Condition** is TRUE), then **Configuration Required** parameters must be programmed.

**Table 1-38. CCDC Conditional Configuration Parameters**

Function	Condition	Configuration Required
VD/HD set as outputs	CCDC_SYN_MODE [0] VDHDOUT = 0x1	CCDC_HD_VD_WID CCDC_PIX_LINES
Interlaced fields	CCDC_SYN_MODE [7] FLDMODE = 0x1	CCDC_CFG [7:6] FIDMD
External WEN	CCDC_SYN_MODE [5] EXWEN = 0x1	CCDC_CFG [8] WENLOG
REC656 input	CCDC_REC656IF [0] R656ON = 0x1 ISP_CTRL [3:2] PAR_BRIDGE = 0x0	CCDC_REC656IF [1] ECCFVH CCDC_CFG [5] BW656
YCC input	CCDC_SYN_MODE [13:12] INPMOD != 0 && CCDC_REC656IF [0] R656ON = 0x0	CCDC_CFG [13] MSBINVI CCDC_DCSUB
8bit YCC Input < 75 MHz	ISP_CTRL [3:2] PAR_BRIDGE = 0x0 CCDC_SYN_MODE [13:12] INPMOD == 2 && CCDC_REC656IF [0] R656ON = 0x0	CCDC_CFG [11] Y8POS
8bit YCC Input < 130 MHz	ISP_CTRL [3:2] PAR_BRIDGE = 0x1    ISP_CTRL [3:2] PAR_BRIDGE = 0x2	
RAW input	CCDC_SYN_MODE [13:12] INPMOD == 0 && CCDC_REC656IF [0] R656ON = 0x0	CCDC_SYN_MODE [10:8] DATSIZ CCDC_CLAMP [31] CLAMPEN
Optical black clamp enabled	CCDC_CLAMP [31] CLAMPEN = 0x1 && CCDC_SYN_MODE [13:12] INPMOD == 0	CCDC_CLAMP [4:0] OBGAIN CCDC_CLAMP [24:10] OBST CCDC_CLAMP [27:25] OBSLN CCDC_CLAMP [30:28] OBSLEN
Optical black clamp disabled	CCDC_CLAMP [31] CLAMPEN = 0x0 && CCDC_SYN_MODE [13:12] INPMOD == 0	CCDC_DCSUB
Faulty-pixel correction	CCDC_FPC [15] FPCEN = 0x1	CCDC_FPC [14:0] FPNUM CCDC_FPC_ADDR Fault Pixel Table must be in memory
Video-port (data formatter) enabled	CCDC_FMTCFG [15] VPEN = 0x1	CCDC_FMTCFG [14:12] VPIN CCDC_FMT_HORZ CCDC_FMT_VERT CCDC_FMTCFG [0] FMTEN CCDC_VP_OUT CCDC_FMTCFG [18:16] VPIF_FRQ
Reformatter enabled	CCDC_FMTCFG [0] FMTEN = 0x1	CCDC_FMTCFG [1] LNALT
Reformatter enabled and line-alternating mode disabled	CCDC_FMTCFG [0] FMTEN = 0x1 && CCDC_FMTCFG [1] LNALT = 0x0	CCDC_FMTCFG [3:2] LNUM CCDC_FMT_ADDRx (x = 0 to 7) CCDC_FMTCFG [11:8] PLEN_EVEN CCDC_FMTCFG [7:4] PLEN_ODD CCDC_PRGEVEN0 or CCDC_PRGEVEN1 CCDC_PRGODD0 or CCDC_PRGODD1

**Table 1-38. CCDC Conditional Configuration Parameters (continued)**

Function	Condition	Configuration Required
Write to memory or resizer	CCDC_SYN_MODE [17] WEN = 0x1    CCDC_SYN_MODE [19] SDR2RSZ = 0x1	CCDC_HORZ_INFO CCDC_VERT_START CCDC_VERT_LINES CCDC_SYN_MODE [14] LPF CCDC_CULLING CCDC_ALAW [3] CCDTBL CCDC_SYN_MODE [11] PACK8 CCDC_CFG [12] BSWD
Write to memory	CCDC_SYN_MODE [17] WEN = 0x1	CCDC_SDR_ADDR CCDC_HSIZE_OFF CCDC_SDOFST
A-Law	CCDC_ALAW [3] CCDTBL = 0x1	CCDC_ALAW [2:0] GWDI
Interrupt usage	VDINT[1:0] Interrupts are enabled	CCDC_VDINT
Lens-shading compensation	CCDC_LSC_CONFIG [0] ENABLE	CCDC_LSC_CONFIG CCSC_LSC_INITIAL CCDC_LSC_TABLE_BASE CCDC_LSC_TABLE_OFFSET

#### 1.5.2.1.3 Pixel Selection (Framing) Register Dependencies

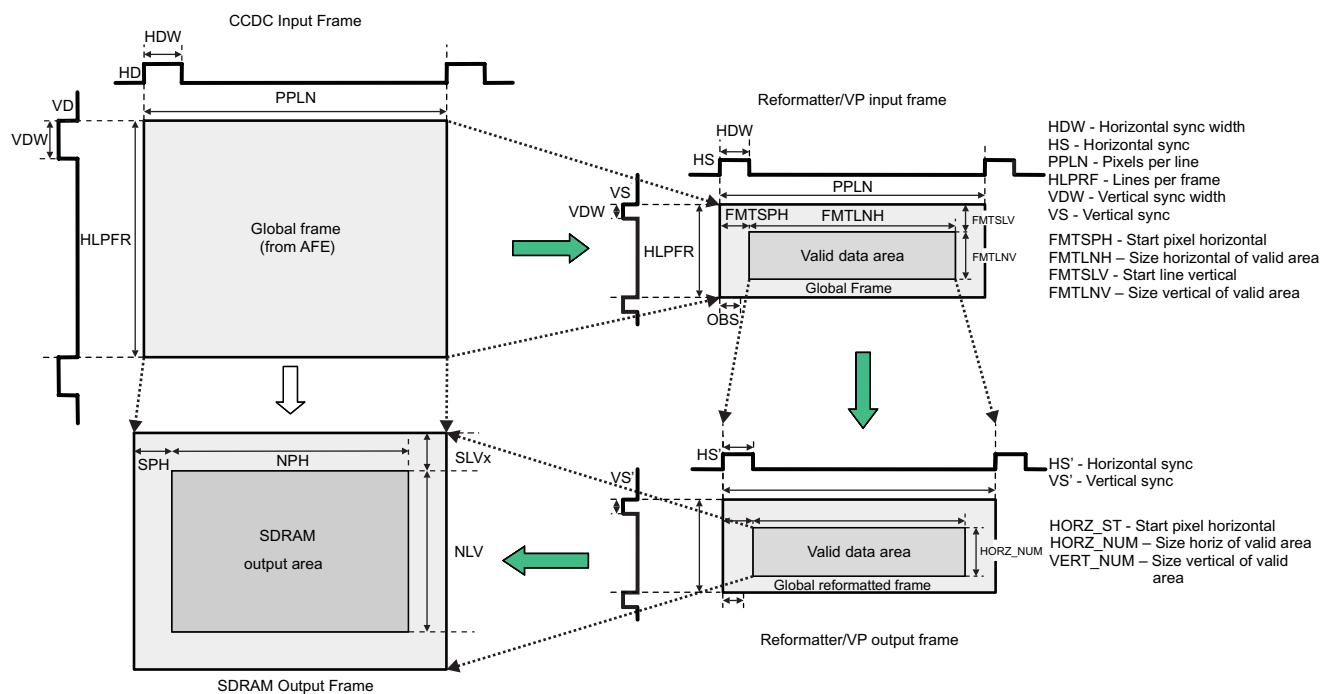

There are three locations in the data flow where the Valid Frame Data can be defined:

- Data Formatter Input Pixel Selection
- Video Port Output Pixel Selection
- Output Formatter Pixel Selection

Care must be taken to ensure that the frame definitions correspond to the output of the upstream frame definitions. When the video port is enabled, CCDC\_VP\_OUT [30:17] VERT\_NUM must be less than CCDC\_FMT\_VERT [12:0] FMTLNv.

Two data paths through the CCDC affect the programming of the pixel-selection registers, depending on the value of the CCDC\_SYN\_MODE [18] VP2SDR bit:

- VP2SDR = 0: The input data bypasses the data formatter/video port. In this case, only the memory output frame parameters apply. This data path is represented by the white arrow in [Figure 1-41](#).
- VP2SDR = 1: The input data passes through the data formatter/video port. In this case, both data formatter frame definitions apply to the video-port output, and all three frame definitions apply to the memory output. This data path is represented by the green shaded arrow in [Figure 1-41](#).

**Figure 1-41. Dependencies Among Framing Settings in Data Flow**

camisp-084

### 1.5.2.2 Enable/Disable Hardware

All required registers mentioned in the previous section must be programmed before setting the CCDC\_PCR [0] ENABLE bit.

The CCDC always operates in continuous mode. In other words, after enabling the CCDC, it processes sequential frames until the ENABLE bit is cleared by software. When this happens, the frame being processed completes before the CCDC is disabled.

When the CCDC is in master mode (HS/VS signals set to outputs), fetching and processing of the frame begin immediately on setting the CCDC\_PCR [0] ENABLE bit.

When the CCDC is in slave mode (HS/VS signals set to inputs), processing of the frame depends on the input timing of the external sensor/decoder. To ensure that data from the external device is not missed, the CCDC must be enabled before data transmission from the external device. In this way, the CCDC waits for data from the external device.

On setting the CCDC\_FPC [15] FPCEN bit, the CCDC begins to fetch and buffer the faulty-pixel table from memory. If faulty-pixel correction is used, the CCDC\_FPC [15] FPCEN bit must be set before the CCDC\_PCR [0] ENABLE bit, but after the faulty-pixel table is placed in memory and the CCDC\_FPC [14:0] FPNUM and CCDC\_FPC\_ADDR registers are set.

### 1.5.2.3 Events and Status Checking

The CCDC can generate three different interrupts: CCDC\_VD0\_IRQ, CCDC\_VD1\_IRQ, and CCDC\_VD2\_IRQ.

The CCDC\_SYN\_MODE [16] VDHEN bit must be enabled to receive any of the CCDC CCDC\_VDx\_IRQ interrupts.

#### 1.5.2.3.1 Interrupts

The CCDC module has 3 programmable events: CCDC\_VD0\_IRQ, CCDC\_VD1\_IRQ, and CCDC\_VD2\_IRQ, and one error event CCDC\_ERR\_IRQ. Event generation is detailed in [Section 1.5.2.3.2](#) and [Section 1.5.2.3.3](#).

CCDC module events can be mapped to the ARM or to the DSP:

- The CCDC\_VD0\_IRQ, CCDC\_VD1\_IRQ, CCDC\_VD2\_IRQ and CCDC\_ERR\_IRQ bits in the ISP\_IRQ0ENABLE register control whether the CCDC module events trigger an interrupt to the ARM. The ISP\_IRQ0STATUS register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the ISP\_IRQ0STATUS register. To clear the CCDC\_ERR\_IRQ interrupt, clear the CCDC\_FPC [16] FPERR bit before clearing the ISP\_IRQ0STATUS [11] CCDC\_ERR\_IRQ bit.
- The CCDC\_VD0\_IRQ, CCDC\_VD1\_IRQ, CCDC\_VD2\_IRQ and CCDC\_ERR\_IRQ bits in the ISP\_IRQ1ENABLE register control whether the CCDC module events trigger an interrupt to the DSP. The ISP\_IRQ1STATUS register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the ISP\_IRQ1STATUS register. To clear the CCDC\_ERR\_IRQ interrupt, clear the CCDC\_FPC [16] FPERR bit before clearing the ISP\_IRQ1STATUS [11] CCDC\_ERR\_IRQ bit.

#### 1.5.2.3.2 CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ Interrupts

As shown in [Figure 1-42](#), CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ interrupts occur relative to the VS pulse. The trigger timing is selected by using the CCDC\_SYN\_MODE [2] VDPOL setting. CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ occur after receiving the number of horizontal lines (HS pulse signals) set in the CCDC\_VDINT [30:16] VDINT0 and CCDC\_VDINT [14:0] VDINT1 register fields, respectively.

**Note:** In the case of BT.656 input mode, there is VS at the beginning of each field. Therefore, there are two interrupts for each frame (one for each field).

If CCDC\_SYN\_MODE [2] VDPOL is 0, the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ HS counters begin counting HS pulses from the rising edge of the external VS, as shown in [Figure 1-42](#).

**Figure 1-42. CCDC\_VD0\_IRQ/CCDC\_VD1\_IRQ Interrupt Behavior When VDPOL = 0**

camisp-085

If CCDC\_SYN\_MODE [2] VDPOL is 1, the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ HS counters begin counting HS pulses from the falling edge of the external VS.

**Figure 1-43. CCDC\_VD0\_IRQ/CCDC\_VD1\_IRQ Interrupt Behavior When VDPOL = 1**

camisp-086

### 1.5.2.3.3 CCDC\_VD2\_IRQ Interrupt

In addition to the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ interrupts, the CCDC has an interrupt called CCDC\_VD2\_IRQ. This interrupt always occurs at the falling edge of the WEN signal (through external pin). There are no registers in the CCDC module to configure this interrupt, see [Figure 1-44](#).

**Figure 1-44. CCDC\_VD2\_IRQ Interrupt Behavior**

camisp-087

### 1.5.2.3.4 Status Checking

The CCDC\_PCR [1] BUSY status bit is set when the start of frame occurs (if the CCDC\_PCR [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The CCDC\_PCR [1] BUSY status bit may be polled to determine end-of-frame status.

The CCDC\_FPC [16] FPERR status bit is set when faulty-pixel data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

### 1.5.2.4 Register Accessibility During Frame Processing

There are three types of register access in the CCDC:

- Shadowed registers: In the CCDC, two register fields are shadowed in different ways. Shadowed registers can be read and written at any time, but the written values take effect (are latched) only at certain times, based on some event. Reads return the most recent write, even though the settings are not used until the specific event occurs. The shadowed registers are:
  - CCDC\_PCR [0] ENABLE
    - Written values take effect only at the start of a frame event (rising edge of VD if CCDC\_SYN\_MODE [2] VDPOL is positive, or falling edge of VD if CCDC\_SYN\_MODE [2] VDPOL is negative).
  - CCDC\_SDR\_ADDR
    - When CCDC\_CFG [15] VDLC is set to 0, written values take effect only at the start of a frame event (rising edge of VD if CCDC\_SYN\_MODE [2] VDPOL is positive, or falling edge of VD if

CCDC\_SYN\_MODE [2] VDPOL is negative). When CCDC\_CFG [15] VDLC is set to 1, written values take effect only at the start of the frame being output to memory (when the input has reached the CCDC\_HORZ\_INFO [30:16] SPH pixel of the CCDC\_VERT\_START [30:16] SLV0 or CCDC\_VERT\_START [14:0] SLV1 line of each field).

- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.  
All register fields in the CCDC not formerly listed as shadowed or below as optionally shadowed/busy-writable are busy-writable registers.
- Optionally Shadowed/Busy-Writable registers: All registers/fields listed below can be set as either shadow registers or busy-writable registers:
  - When CCDC\_CFG [15] VDLC is 0, these registers are shadowed.
  - When CCDC\_CFG [15] VDLC is 1, these registers are busy-writable.

---

**Note:** CCDC\_CFG [15] VDLC must be set to 1 by software if the CCDC is to be used; therefore, these registers are busy-writable. If CCDC\_CFG [15] VDLC remains set to 0 (default), indeterminate results may occur for ANY register access in the CCDC, not just those listed below.

---

- Optionally shadowed or busy-writable registers
  - CCDC\_SYN\_MODE [19] SDR2RSZ
  - CCDC\_SYN\_MODE [18] VP2SDR
  - CCDC\_SYN\_MODE [16] VDHEN
  - CCDC\_SYN\_MODE [17] WEN
  - CCDC\_SYN\_MODE [14] LPF
  - CCDC\_HD\_VD\_WID
  - CCDC\_PIX\_LINES
  - CCDC\_HORZ\_INFO
  - CCDC\_VERT\_START
  - CCDC\_VERT\_LINES
  - CCDC\_CULLING
  - CCDC\_HSIZE\_OFF
  - CCDC\_SDOFST
  - CCDC\_CLAMP [31] CLAMPEN
  - CCDC\_FMTCFG [0] FMTEN
  - CCDC\_LSC\_CONFIG
  - CCDC\_LSC\_INITIAL
  - CCDC\_LSC\_TABLE\_BASE
  - CCDC\_LSC\_TABLE\_OFFSET

### 1.5.2.5 Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Since the CCDC\_PCR register and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

### 1.5.2.6 CCDC Operations

#### 1.5.2.6.1 Image-Sensor Configuration

### 1.5.2.6.1.1 Input-Mode Selection

The CCDC module supports two modes: SYNC mode and ITU-R BT.656 mode. Specific settings correspond to each mode.

- SYNC mode:
  - In this mode, the input data can be either raw data or YCbCr data. Setting CCDC\_SYN\_MODE.INPMODE = 0 selects raw data, and CCDC\_SYN\_MODE [13:12] INPMODE = 1 or 2 selects YCbCr data on 16 or 8 bits. If CCDC\_SYN\_MODE[13:12] INPMODE = 0, the cam\_d signal width is selected through CCDC\_SYN\_MODE [10:8] DATSIZ: the possible values are 8, 10, 11, and 12 bits.
  - If CCDC\_SYN\_MODE [13:12] INPMODE = 1, the cam\_d signal width is 8 bits, but the internal CCDC module data path is configured to 16 bits. It is mandatory to enable the 8- to 16-bit bridge by setting ISP\_CTRL [3:2] PAR\_BRIDGE = 2 or 3. The ISP\_CTRL [3:2] PAR\_BRIDGE bit also controls how the 8-bit data is mapped onto the 16-bit data.
  - The value set in CCDC\_SYN\_MODE [10:8] DATSIZ does not matter. The position of the Y component can be set with the CCDC\_CFG [11] Y8POS bit.
  - If CCDC\_SYN\_MODE [13:12] INPMODE = 2, the cam\_d signal width is 8 bits. The value set in CCDC\_SYN\_MODE [10:8] DATSIZ does not matter. The position of the Y component can be set with the CCDC\_CFG [11] Y8POS bit.
  - The internal timing generator must be enabled with CCDC\_SYN\_MODE [16] VDHDEN = 1.
- ITU mode:
  - In this mode, the data follows the protocol set by the ITU-R BT.656 protocol. To select it, set CCDC\_REC656IF [0] R656ON = 1. When this mode is selected, the values set in CCDC\_SYN\_MODE [13:12] INPMODE and CCDC\_SYN\_MODE [10:8] DATSIZ do not matter.
  - To select the 8-bit or 10-bit protocol, set the CCDC\_CFG [5] BW656 bit field. Data line cam\_d [7:0] are used for 8-bit YCbCr and cam\_d [9:0] are used for 10-bit YCbCr.
  - FVH error correction is enabled by setting CCDC\_REC656IF [1] ECCFVH = 1.
  - The internal timing generator must be enabled with CCDC\_SYN\_MODE [16] VDHDEN = 1.

### 1.5.2.6.1.2 Timing Generator and Frame Settings

The polarities of the cam\_hs, cam\_vs and cam\_fld signals are controlled by the CCDC\_SYN\_MODE [3] HDPOL, CCDC\_SYN\_MODE [2] VDPOL, and CCDC\_SYN\_MODE [4] FLDPOL bit fields. The polarities can be positive or negative.

The pixel data is presented on cam\_d one pixel for every cam\_pclk rising edge or falling edge. It is controlled with the ISP\_CTRL [4] PAR\_CLK\_POL bit.

The CCDC\_SYN\_MODE [7] FLDMODE bit fields set the image-sensor type to progressive or interlaced mode. When the sensor is interlaced, the CCDC\_SYN\_MODE [15] FLDSTAT status bit indicates whether the current frame is odd or even.

The polarity of the cam\_d signal can also be controlled with the CCDC\_SYN\_MODE [6] DATAPOL bit field. The polarity can be normal mode or one's complement mode.

Furthermore, the directions of the cam\_fld and cam\_hs/cam\_vs signals are controlled by the CCDC\_SYN\_MODE [1] FLDOOUT and CCDC\_SYN\_MODE [0] VDHDOUT bits. If CCDC\_SYN\_MODE [0] VDHDOUT is set as an output, the CCDC\_PIX\_LINES register controls the length of the cam\_hs and cam\_vs signals.

If CCDC\_SYN\_MODE [0] VDHDOUT = 1:

- The HS sync pulse width is given by CCDC\_HD\_VD\_WID [27:16] HDW. The VS sync pulse width is given by CCDC\_HD\_VD [11:0] VDW.
- The HS period is given by CCDC\_PIX\_LINES [31:16] PPLN. The VS period is given by CCDC\_PIX\_LINES [15:0] HLPF x 2.

Figure 1-45 shows the HS/VS sync pulse output timings.

**Figure 1-45. HS/VS Sync Pulse Output Timings**

camisp-117

### 1.5.2.6.1.3 Mosaic Filter Settings

The CCDC module supports image sensors with R, G, and B primary color mosaic filters and Ye, Cy, Mg, and G complementary color mosaic filters. The mosaic filter layout pattern is controlled by the `CCDC_COLPTN` register. Each bit field in this register controls the color associated to one pixel in a 4x4 region area. The 4x4 area repeats horizontally and vertically.

Figure 1-46 shows configuration examples of the `CCDC_COLPTN` register. It is assumed that `CP0LPC0` is the first pixel output and `CP3LPC3` is the last pixel output during frame readout.

**Figure 1-46. Mosaic Filter - CCDC\_COLPTN Bit Field Settings**

### 1.5.2.6.2 Image-Signal Processing

#### 1.5.2.6.2.1 Digital Clamp

Digital clamp is enabled only if optical black clamping is disabled: CCDC\_CLAMP [31] CLAMPEN = 0. The digital clamp DC value to be subtracted from the raw image data (CCDC\_SYN\_MODE [13:12] INPMOD = 0) or from the luminance (CCDC\_SYN\_MODE [13:12] INPMOD = 0 or CCDC\_REC656IF [0] R656ON = 1) is set with the CCDC\_DCSUB register. The DC value can range from 0 to 212-1. The reset value is 0.

#### 1.5.2.6.2.2 Optical Black Clamping

Optical black clamping is enabled by setting CCDC\_CLAMP [31] CLAMPEN to 1. When enabled, an average of black-pixel samples is computed over a window. If the window's height is 2N, the average value multiplied by a programmable gain factor is subtracted from the raw image data for the following 2N lines. Every 2N lines, a new average value is computed. For the first 2N lines, 0 is subtracted.

The window's size and horizontal position are controlled by the CCDC\_CLAMP register. The window's vertical position is set to line 0 and cannot be modified:

- CCDC\_CLAMP [30:28] OBSLEN sets the horizontal size of the window (1, 2, 4 or 8 pixels).
- CCDC\_CLAMP [27:25] OBSLN sets the vertical size of the window (2N = 1, 2, 4 or 8 lines).
- CCDC\_CLAMP [24:10] OBST sets the horizontal start position of the upper-left corner of the window. It is specified from the start of the HS sync pulse in pixel clocks.

The gain factor is set by the CCDC\_CLAMP [4:0] OBGAIN bit field. Its fixed-point representation is U5Q4; the range is 0 to 1.9375. The gain factor reset value is 1.

If optical-black clamping is disabled, digital clamp is enabled.

#### 1.5.2.6.2.3 Black Compensation

Black compensation applies an offset to the raw image data. The offset is applied according to the phase and color for each phase. The black compensation offsets are controlled by the CCDC\_BLKCOMP register. All offsets are coded in S8Q0 representation (two's complement); the range is -128 to +127.

#### 1.5.2.6.2.4 Faulty-Pixel Correction

Faulty-pixel correction is enabled by setting CCDC\_FPC [15] FPCEN to 1. Before activating faulty-pixel correction, set the number of faulty pixels to be corrected in a frame with the CCDC\_FPC [14:0] FPNUM bit field, set the faulty-pixel LUT in memory, and set the CCDC\_FPC\_ADDR register to the LUT address. The address should be aligned to a 64-bit byte boundary; the 6 LSBs are ignored. Reading the register always shows the 6 LSBs as 0.

If the CCDC module cannot fetch the required faulty-pixel entry in time, an error is set in the CCDC\_FPC [16] FPERR bit. After the bit is set, no more faulty pixels are corrected in the frame. The bit is automatically cleared on the end of the frame and the feature reenabled for the following frame.

#### 1.5.2.6.2.5 Lens Shading Compensation

Lens Shading Compensation operates either on a single frame or continuously depending on firmware programming. Upon power-on reset, the LSC module is disabled and input pixels are copied to the output, bypassing any shading operation.

Prior to enabling the LSC module the configuration registers must be initialized.

The SBL data read port is shared between the CCDC shading compensation and PREVIEW dark frame subtract features. The read port must be affected to the PREVIEW module by writing 1 into the ISP\_CTRL [28] SBL\_SHARED\_RPORTB. Programmers must ensure that the PREVIEW module does not use this port before switching to CCDC module.

The following registers define the gain map organization. The must be configured for correct operation:

- CCDC\_LSC\_TABLE\_OFFSET: Rows length of the gain
- CCDC\_LSC\_CONFIG [10:8] GAIN\_MODE\_N: Vertical downsampling factor
- CCDC\_LSC\_CONFIG [14:12] GAIN\_MODE\_M: Horizontal downsampling factor
- CCDC\_LSC\_CONFIG [3:1] GAIN\_FORMAT: Gain map samples coding

Firmware chooses the position of the LSC module in the data flow using the CCDC\_LSC\_CONFIG [6] AFTER\_REFORMATTER register. Image framing is set using the registers listed below:

- Before data reformatter. Framing is applied to the image received from the sensor.
  - CCDC\_FMT\_HORZ[28:16] FMTSPH: First horizontal pixel from HS sync pulse
  - CCDC\_FMT\_HORZ[12:0] FMTLNH: Number of pixels in horizontal direction
  - CCDC\_FMT\_VERT[28:16] FMTSLV: First line from VS sync pulse
  - CCDC\_FMT\_VERT[12:0] FMTLNV: Number of lines
- After data reformatter. Framing is applied to the image received from data formatter. Therefore the frame size depends on data reformatter settings.
  - CCDC\_VP\_OUT[30:17] VERT\_NUM: Number of lines
  - CCDC\_VP\_OUT[16:4] HORZ\_NUM: Number of pixels in horizontal direction
  - CCDC\_VP\_OUT[3:0] HORZ\_ST: First horizontal pixel

CCDC\_LSC\_TABLE\_BASE must point to the first used gain sample. The first pixels phase is defined by the CCDC\_LSC\_INITIAL [5:0] X and CCDC\_LSC\_INITIAL [21:16] Y registers. They must be consistent with the gain map organization and the defined framing.

When CCDC\_LSC\_CONFIG [0] ENABLE bit is written 1, the LSC module starts operation by prefetching needed gain entries from external memory, and when the active region starts, appropriate gains are applied to the image pixels. Refer to for more details on gain map organization.

When the LSC module reaches the last N lines of the input image (with respect to starting gain map point, which may or may not coincide with starting of active region of image), it detects the CCDC\_LSC\_CONFIG [0] ENABLE bit. If CCDC\_LSC\_CONFIG [0] ENABLE = 1, it starts prefetching gain entries for the next frame and wait for the active region of next frame to arrive. If CCDC\_LSC\_CONFIG [0] ENABLE = 0, it stops LSC operation once the active region is passed, and goes into idle until CCDC\_LSC\_CONFIG [0] ENABLE is written 1 again. To provide a mechanism for firmware to recover from LSC module waiting for input image indefinitely, if CCDC\_LSC\_CONFIG [0] ENABLE is written 0 after it has started gain map prefetching, but before LSC gets to the next active region, LSC operation is aborted and turned idle, with any prefetched gain entries are discarded. This can happen before or after the next start of frame.

LSC registers are optionally shadowed. When they are shadowed they can be modified at any time. The new value is taken into account for the next frame. Otherwise the module must be disabled (CCDC\_LSC\_CONFIG [0] ENABLE=0) prior to changing non shadowed registers.

### 1.5.2.6.2.6 Data Formatter

The data formatter transforms movie mode readout patterns into Bayer readout patterns. It is enabled by setting CCDC\_FMTCFG [0] FMTEN to 1.

The CCDC\_FMT\_HORZ and CCDC\_FMT\_VERT registers set a clip window at the input of the data reformatter.

The data formatter converts a single line of movie mode sensor into multiple Bayer lines; it is capable of transforming 1 input line into 1, 2, 3, or 4 output lines. The number of lines generated from one input line is set by the CCDC\_FMTCFG [3:2] LNUM bit field. The following limitations apply:

- The maximum number of pixels that can be supported in an output line if the input line is transformed into 1 output line is 4x1376 (1376 is the limit of the line memory).
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 2 output lines is 2x1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 3 output lines is 1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 4 output lines is 1376.

The data reformatter gets its flexibility from up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. The program length for even fields is set with the CCDC\_FMTCFG [11:8] PLEN\_EVEN bit field. The program length for odd fields is set with the CCDC\_FMTCFG [7:4] PLEN\_ODD bit fields. Each entry refers to one of the 8 addresses and supports autoincrement and autodecrement.

- The 8 addresses are controlled by the CCDC\_FMT\_ADDRx registers (x = 0 to 7).
- The 16 program entries for even lines are controlled by the CCDC\_PRGEVEN0 and CCDC\_PRGEVEN1 registers. The 16 program entries for odd lines are controlled by the CCDC\_PRGODD0 and CCDC\_PRGODD1 registers.

Modulo addressing is used to access the program entries. Even input lines use the even program and odd input lines use the odd program. Each new pixel in a line uses one program entry.

The CCDC\_VP\_OUT register sets the frame size at the output of the video port.

#### Example 1: Conventional readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 1-39](#)) corresponds to a conventional readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

**Table 1-39. Conventional Readout Pattern 1 to 1**

Input	Pixels order in input line								
Line [I]	0	1	2	3	[...]	5500	5501	5502	5503
Output	Pixels order in output line								
Line [I]	0	1	2	3	[...]	5500	5501	5502	5503

To obtain this mapping between the input and output pixels, the following settings apply:

- |                                       |     |                                |
|---------------------------------------|-----|--------------------------------|
| - CCDC_FMTCFG [3:2] LNUM              | = 0 | Converts to 1 line             |
| - CCDC_FMTCFG [11:8] PLEN_EVEN        | = 0 | 1 program entry                |
| - CCDC_FMTCFG [7:4] PLEN_ODD          | = 0 | 1 program entry                |
| - CCDC_FMT_ADDRx [25:24] LINE (x = 0) | = 0 | Init ADDR0 pointer to 0th line |
| - CCDC_FMT_ADDRx [12:0] INIT (x = 0)  | = 0 | Init ADDR0 index to 0th pixel  |
| - CCDC_PRGEVEN0 [3:0] EVEN0           | = 0 | Even prog entry 0: ADDR0++     |
| - CCDC_PRGODD0 [3:0] ODD0             | = 0 | Odd prog entry 0: ADDR0++      |
| - CCDC_VP_OUT [3:0] HORZ_ST           | = 0 | Horizontal start               |

- CCDC\_VP\_OUT [16:4] HORZ\_NUM = 0 Horizontal size

The program for even and odd lines is executed as follows. Since there is only one program entry, this instruction is executed repeatedly.

```
ADDR0= (0, 0)
While not end_of_line
{
Write
    incoming pixel to ADDR0
ADDR0+=(1,0)
}
```

### Example 2: Dual readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 1-40](#)) corresponds to a conventional dual readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

**Table 1-40. Dual Readout Pattern 1 to 1**

Input	Pixels order in input line								
Line [I]	0	1	2	3	...	4092	4093	4094	4095
Output	Pixels order in output line								
Line [I]	0	2	4	6	...	7	5	3	1

To obtain this mapping between the input and output pixels, the following settings apply:

- CCDC\_FMTCFG [3:2] LNUM = 0 Converts to 1 line  
- CCDC\_FMTCFG [11:8] PLEN\_EVEN = 1 2 program entry  
- CCDC\_FMTCFG [7:4] PLEN\_ODD = 1 2 program entry  
- CCDC\_FMT\_ADDRx [25:24] LINE (x = 0) = 0 Init ADDR0 pointer to 0th line  
- CCDC\_FMT\_ADDRx [12:0] INIT (x = 0) = 0 Init ADDR0 index to 0th pixel  
- CCDC\_FMT\_ADDRx [25:24] LINE (x = 1) = 0 Init ADDR1 pointer to 0th line  
- CCDC\_FMT\_ADDRx [12:0] INIT (x = 1) = 4095 Init ADDR1 index to 4095th pixel  
- CCDC\_PRGEVEN0 [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++  
- CCDC\_PRGEVEN0 [7:4] EVEN1 = 3 Even prog entry 1: ADDR1- -  
- CCDC\_PRGODD0 [3:0] ODD0 = 0 Even prog entry 0: ADDR0++  
- CCDC\_PRGODD0 [7:4] ODD1 = 3 Even prog entry 1: ADDR1- -  
- CCDC\_VP\_OUT [3:0] HORZ\_ST = 0 Horizontal start  
- CCDC\_VP\_OUT [16:4] HORZ\_NUM = 0 Horizontal size

```
ADDR0=(0,0)
ADDR1=(4095,0)
While not
    end_of_line
{
Write incoming pixel to ADDR0
ADDR0+= (1,0)
Write incoming pixel to ADDR1
ADDR1 -= (1,0)
}
```

### Example 3: Dual readout pattern: 1 input line = 3 output line

The following input-to-output mapping (see [Table 1-41](#)) corresponds to a complex pattern. One input line corresponds to 3 output lines; the output can be as large as 1376 pixels.

**Table 1-41. Dual Readout Pattern 1 to 3**

Input	Pixels order in input line								
Line [i]	0	1	2	3	4	5	6	7	8
	9	10	11	[...]					
Output	Pixels order in output line								
Line [3i]			0	6	[...]	23	17	11	5
Line [3i + 1]		2	8	14	[...]	15	9	3	
Line [3i + 2]	4	10	16	22	[...]	7	1		

To obtain this mapping between the input and output pixels, the following settings apply:

- CCDC_FMTCFG [3:2] LNUM	= 2	Converts to 3 lines
- CCDC_FMTCFG [11:8] PLEN_EVEN	= 5	6 program entries
- CCDC_FMTCFG [7:4] PLEN_ODD	= 5	6 program entries
- CCDC_FMT_ADDRx [25:24] LINE (x = 0)	= 0	Init ADDR0 pointer to 0th line
- CCDC_FMT_ADDRx [12:0] INIT (x = 0)	= 2	Init ADDR0 index to 2nd pixel
- CCDC_FMT_ADDRx [25:24] LINE (x = 1)	= 2	Init ADDR1 pointer to 2nd line
- CCDC_FMT_ADDRx [12:0] INIT (x = 1)	= 855	Init ADDR1 index to 855th pixel
- CCDC_FMT_ADDRx [25:24] LINE (x = 2)	= 1	Init ADDR2 pointer to first line
- CCDC_FMT_ADDRx [12:0] INIT (x = 2)	= 1	Init ADDR2 index to first pixel
- CCDC_FMT_ADDRx [25:24] LINE (x = 3)	= 1	Init ADDR3 pointer to first line
- CCDC_FMT_ADDRx [12:0] INIT (x = 3)	= 856	Init ADDR3 index to 856th pixel
- CCDC_FMT_ADDRx [25:24] LINE (x = 4)	= 2	Init ADDR4 pointer to second line
- CCDC_FMT_ADDRx [12:0] INIT (x = 4)	= 0	Init ADDR4 index to 0th pixel
- CCDC_FMT_ADDRx [25:24] LINE (x = 5)	= 0	Init ADDR5 pointer to 0th line
- CCDC_FMT_ADDRx [12:0] INIT (x = 5)	= 857	Init ADDR5 index to 857th pixel
- CCDC_PRGEVEN0 [3:0] EVEN0	= 0	Even prog entry 0: ADDR0++
- CCDC_PRGEVEN0 [7:4] EVEN1	= 3	Even prog entry 1: ADDR1- -
- CCDC_PRGEVEN0 [11:8] EVEN2	= 4	Even prog entry 2: ADDR2++
- CCDC_PRGEVEN0 [15:12] EVEN3	= 7	Even prog entry 3: ADDR3- -
- CCDC_PRGEVEN0 [19:16] EVEN4	= 8	Even prog entry 4: ADDR4++
- CCDC_PRGEVEN0 [23:20] EVEN5	= 11	Even prog entry 4: ADDR5- -
- CCDC_PRGODD0 [3:0] ODD0	= 0	Even prog entry 0: ADDR0++
- CCDC_PRGODD0 [7:4] ODD1	= 3	Even prog entry 1: ADDR1- -
- CCDC_PRGODD0 [11:8] ODD2	= 4	Even prog entry 2: ADDR2++
- CCDC_PRGODD0 [15:12] ODD3	= 7	Even prog entry 3: ADDR3- -
- CCDC_PRGODD0 [19:16] ODD4	= 8	Even prog entry 4: ADDR4++
- CCDC_PRGODD0 [23:20] ODD5	= 11	Even prog entry 4: ADDR5- -
- CCDC_VP_OUT [3:0] HORZ_ST	= 2	Horizontal start, excludes first 2 pixels
- CCDC_VP_OUT [16:4] HORZ_NUM	= 854	Horizontal size

```

ADDR0=(2,0)
ADDR1=(855,2)
ADDR2=(1,1)
ADDR3=(856,1)
ADDR4=(0,2)
ADDR5=(857,0)
While
    not end_of_line
{
Write incoming pixel to
    ADDR0
ADDR0 += (1, 0)
Write incoming pixel to
    ADDR1
ADDR1 -= (1, 0)
Write incoming pixel to
    ADDR2
ADDR2 += (1, 0)
Write incoming pixel to
    ADDR3
ADDR3 -= (1, 0)
Write incoming pixel to
    ADDR4
ADDR4 += (1, 0)
Write incoming pixel to
    ADDR5
ADDR5 -= (1, 0)
}

```

## Video Port

The 10-bit video-port output is enabled with CCDC\_FMTCFG [15] VPEN = 1. Since the input data can be up to 12 bits, one has to select which 10 bits are selected with CCDC\_FMTCFG [14:12] VPIN.

The output of the video port goes to the Preview module. At the output of the video port, the data rate is resynchronized; the CCDC\_FMTCFG [18:16] VPIF\_FRQ bit field selects the video-output data rate (from L3/2 MHz to L3/6 MHz). If CCDC\_FMTCFG [18:16] VPIF\_FRQ frequency is set too low compared to the input pixel clock, overflow can occur.

### 1.5.2.6.2.7 Output Formatter

#### 1.5.2.6.2.7.1 Low-Pass Filter

The low-pass filter is enabled with the CCDC\_SYN\_MODE [14] LPF bit. When enabled, two pixels each in the left and right edges of each line are cropped from the output.

#### 1.5.2.6.2.7.2 A-Law Compression

A-Law compression is enabled by setting CCDC\_ALAW [3] CCDTBL to 1. The A-Law table is fixed, so no setup is required. When the input is wider than 10 bits, the CCDC\_ALAW [2:0] GWDI bit is used to select which 10 bits of the 12 possible bits are selected for compression. See [Table 1-42](#).

**Table 1-42. CCDC\_ALAW [2:0] GWDI**

GWDI	Description
4	Bits 11 to 2
5	Bits 10 to 1
6	Bits 9 to 0
Others	Reserved

### 1.5.2.6.2.7.3 Culling

Culling performs a horizontal and vertical decimation function. The horizontal and vertical culling patterns are set by the CCDC\_CULLING register.

- The 8-bit CCDC\_CULLING [31:24] CULHEVN and CCDC\_CULLING [23:16] CULHODD bit fields set the horizontal culling pattern for even and odd lines. A 1 means that the pixel is retained; a 0 means that the pixel is skipped. The same number of retained pixels must be set for even and odd lines.
- The 8-bit CCDC\_CULLING [7:0] CULV bit field sets the vertical culling pattern. The LSB represents the top line and the MSB represents the bottom line. A 1 means that the line is retained; a 0 means that the line is skipped.

### 1.5.2.6.2.7.4 Data Packing

Pixel data are stored to memory in little-endian format (bytes at lower addresses have lower significance). By default, pixel data are stored in 16-bit words; unused bits are filled with zeros.

If the input data is 8 bits, or if A-Law compression is enabled, one can store the data into 8-bit words by setting CCDC\_SYN\_MODE [11] PACK8 to 1.

If the input data is 12, 11, 10, or 9 bits, and A-Law compression is not enabled, the 8 MSBs are stored to memory.

Figure 1-47 shows data packing and pixel ordering.

**Figure 1-47. Data Packing - Pixel Ordering**

	3 1	2 4	1 5	0 7	0 0
12 bits	0	pix 1	0	pix 0	
11 bits	0	pix 1	0	pix 0	
10 bits	0	pix 1	0	pix 0	
9 bits	0	pix 1	0	pix 0	
8 bits	0	pix 1	0	pix 0	
8 bits packed	pix3	pix 2	pix 1	pix 0	

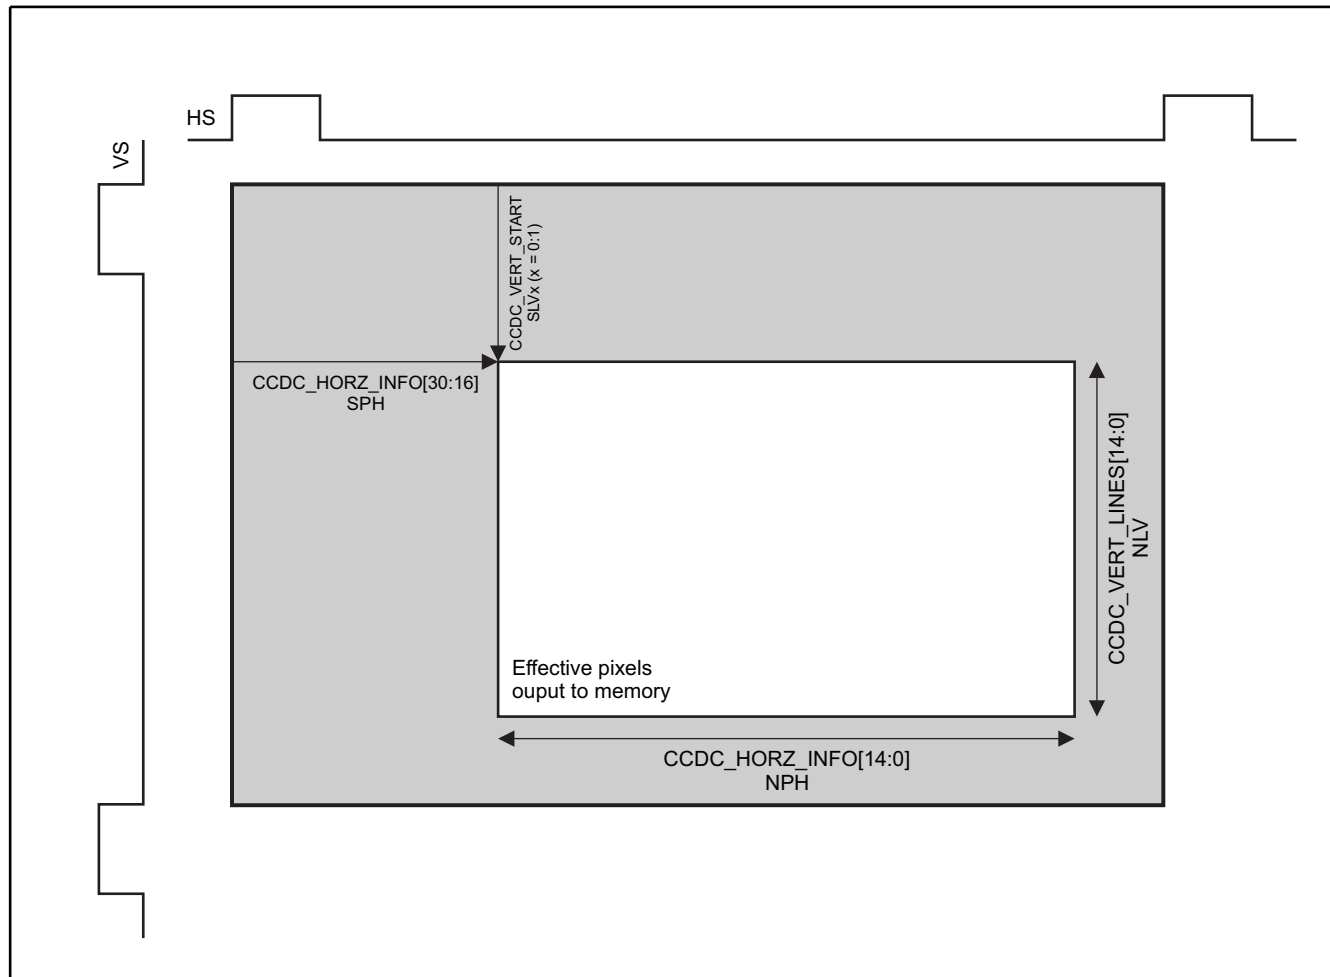

camisp-118

### 1.5.2.6.2.7.5 Clipping Window

Before data is stored in memory, one can set a clipping window; only a selected sensor area is stored to memory. Figure 1-48 shows the settings; only the white area is stored to memory.

- The valid-data horizontal start position is controlled with the CCDC\_HORZ\_INFO [30:16] SPH bit field. The valid-data vertical start position is controlled with the CCDC\_VERT\_START register. If the sensor is interlaced, the vertical start position for even and odd fields can be configured independently with the CCDC\_VERT\_START register. If the sensor is progressive, the CCDC\_VERT\_START [14:0] SLV1 bit field is ignored.
- The valid-data horizontal size is controlled with the CCDC\_HORZ\_INFO [14:0] NPH bit field. The horizontal size must be a multiple of 16 pixels. The valid-data vertical size is controlled with the CCDC\_VERT\_LINES [14:0] NLV register.

**Figure 1-48. Clipping Window Before Output to Memory**

camisp-119

#### 1.5.2.6.2.7.6 Output to Memory

The output formatter memory write enable is controlled by the CCDC\_SYN\_MODE [17] WEN bit. The output of the data reformatter can be written to memory by setting CCDC\_SYN\_MODE [18] VP2SDR to 1.

The pixel data at the output of the output formatter is written to the address given by the `CCDC_SDR_ADDR` register. The address should be aligned on a 32-byte boundary. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0.

A destination pitch can be set with the `CCDC_HSIZE_OFF` register. The offset must be a multiple of 32 bytes. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0. It is required for the pixel line length to be a multiple of 32 bytes to be stored in memory without holes.

The CCDC\_SDOFST register controls how the pixels are stored to memory.

Data to be written to memory can be qualified by the external `cam_wen` signal. This feature can be enabled by setting the `CCDC_SYN_MODE` [5] `EXWEN` bit. The `CCDC_CFG` [8] `WENLOG` bit configures how the `cam_wen` signal is used with the internally generated valid signal.

The data can be swapped on a byte basis with the CCDC\_CFG [12] BSWD bit.

If CCDC\_SYN\_MODE [13:12] INPMOD = 1, the MSB of the 8-bit chroma component can be inverted by setting CCDC\_CFG [13] MSBINVI to 1.

### 1.5.2.7 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the CCDIC. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- If faulty-pixel correction is enabled, the CCDIC\_FPC\_ADDR address should be on a 64-byte boundary.
- External WEN cannot be used when the VP2SDR path is enabled.
- If the formatter is enabled, in line-alternating mode, the vertical start and end number should be even.
- The horizontal number for the video port must be  $\leq 1376 \times 4$ .
- If the video port is enabled, CCDIC\_VP\_OUT [30:17] VERT\_NUM must be CCDIC\_FMT\_VERT [12:0] FMTLNV.
- The video port must be enabled if the formatter is enabled.
- In YCC input mode:
  - The CCDIC\_COLPTN must be set to 0s.
  - The CCDIC\_BLKCOMP must be set to 0s.
  - Faulty-pixel correction must be disabled.
  - The video port must be disabled.
  - The formatter must be disabled.
  - The VP2SDR must be disabled.
  - The low-pass filter must be disabled.
  - The A-Law must be disabled.
- In RAW input mode, the resizer output path should not be enabled.

## 1.5.3 Programming the Preview Engine

This section discusses issues related to software control of the preview engine. It lists which registers are required to be programmed in different modes, how to enable and disable the preview engine, and how to check the status of the preview engine; discusses the different register access types; and enumerates programming constraints.

### 1.5.3.1 Preview Hardware Setup/Initialization

This section discusses the configuration of the preview engine required before image processing can begin.

#### 1.5.3.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the preview engine are reset to their reset values. However, since the preview engine programmable tables (gamma, noise filter, luminance enhancer, and CFA coefficients) are stored in internal memory, their contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of these tables are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of these tables remain the same as before the reset.

#### 1.5.3.1.2 Register Setup

Before enabling the preview engine, the hardware must be correctly configured through register writes. [Table 1-43](#) identifies the register parameters that must be programmed before enabling the preview engine.

**Table 1-43. Preview Engine Required Configuration Parameters**

Function	Configuration Required
Function enable/disable	PRV_PCR [5] INVALAW
	PRV_PCR [7] DRKFCAP
	PRV_PCR [6] DRKFEN
	PRV_PCR [21] SCOMP_EN
	PRV_PCR [8] HMEDEN
	PRV_PCR [9] NFEN
	PRV_PCR [10] CFAEN
	PRV_PCR [26] GAMMA_BYPASS
	PRV_PCR [15] YNENHEN
	PRV_PCR [16] SUPEN

	PRV_PCR [18:17] YCPOS

The PRV\_PCR register contains control bits that enable or disable optional functions and module I/O ports. If an optional function or port is enabled, there may be more registers or configuration information required for the preview engine to operate correctly.

[Table 1-44](#) can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters must be programmed.

**Table 1-44. Preview Engine Conditional Configuration Parameters**

Function	Condition	Configuration Required
Read from CCDC	PRV_PCR [2] SOURCE = 0x0	PRV_PCR [3] ONESHOT
Read from memory	PRV_PCR [2] SOURCE = 0x1	PRV_PCR [4] WIDTH
		PRV_RSDR_ADDR
		PRV_RADR_OFFSET
		ISP_CTRL [27] SBL_SHARED_RPORTA
Dark frame subtract	PRV_PCR [6] DRKFEN = 0x1	PRV_DSDR_ADDR
		PRV_DRKF_OFFSET
		ISP_CTRL [28] SBL_SHARED_RPORTB
		Dark frame must be in memory

Write to memory	PRV_PCR [20] SDRPORT = 0x1	PRV_WSDR_ADDR PRV_WADD_OFFSET

### 1.5.3.1.3 Table Setup

The three gamma memories, noise filter threshold memory, noise filter strength memory, luminance enhancer memory, and the CFA coefficient memory must be filled in before the operation of the preview engine, if their respective functions are enabled.

Two registers allow memory contents to be read and written:

- The address register is used to select the specific table entry: PRV\_SET\_TBL\_ADDR.
- The data register contains the data to be written to the specified location: PRV\_SET\_TBL\_DATA.

While the data register is 20 bits wide, only the 8 LSB data is used for the gamma, noise filter, and CFA filter tap memories. [Table 1-45](#) identifies the addressing range for each memory provided in the preview engine.

**Table 1-45. Preview Engine Memory Address Ranges**

Start	End	Bit Width	Memory
0x0000	0x03FF	8	Red gamma table
0x0400	0x07FF	8	Green gamma table
0x0800	0x0BFF	8	Blue gamma table
0x0C00	0x0C1F	10	NF threshold table 32x10
0x0C20	0x0C3F	5	NF strength table 32x5
0x1000	0x107F	20	Non-linear enhancement table
0x1400	0x163F	8	CFA filter coefficient table

The preview engine supports linear increments on reads and writes automatically. The following examples show how the programmer can read/write the memory. If data is read/written, the address pointer is automatically incremented. For random/noncontiguous reads/writes, PRV\_SET\_TBL\_ADDR register must be modified.

**Note:** The address is not autoincremented when the preview engine is busy and users try to read/write the tables.

### Example:

*Read/write all the entries of the CFA table (using linear increment):*

- WRITE (SET\_TBL\_ADDR, 0x1400);
- READ (SET\_TBL\_DATA, 0xvalue1);
- WRITE (SET\_TBL\_DATA, 0xvalue2);
- READ (SET\_TBL\_DATA, 0xvalue3);
- Etc. . . .
- READ (SET\_TBL\_DATA, 0xvalue163F);

**Read/write selective entries of the tables (have to program the address separately for each read/write)**

- WRITE (SET\_TBL\_ADDR, 11);
- READ (SET\_TBL\_DATA, value11);
- WRITE (SET\_TBL\_ADDR, 564);
- WRITE (SET\_TBL\_DATA, value564);

### 1.5.3.2 Enable/Disable Hardware

Setting the PRV\_PCR [0] ENABLE bit to 0x1 enables the preview engine. This must be done after all required registers and tables are programmed.

When the input source is the memory, the preview engine always operates in one-shot mode. In other words, after enabling the preview engine, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCDC, the preview engine can be configured to operate in either one-shot mode or continuous mode (PRV\_PCR [3] ONESHOT). Processing of the frame is depends on the timing of the CCDC. To ensure that data from the CCDC is not missed, the preview engine must be enabled before the CCDC so that it waits for CCDC data.

---

**Note:** In one-shot mode, on setting the ENABLE bit, the processing of the frame begins and the ENABLE, ONESHOT, and SOURCE bits are reset to their reset values.

---

When the preview engine is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

### 1.5.3.3 Events and Status Checking

The preview engine generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the ISP\_IRQ0STATUS register (or ISP\_IRQ1STATUS). When the read of the register ISP\_IRQ0STATUS occurs (or ISP\_IRQ1STATUS), the register is not automatically reset. To reset the interrupt, a 1 must be written to the PRV\_DONE\_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the ISP\_IRQ0ENABLE register (or ISP\_IRQ1ENABLE). When a particular event is not enabled (for example ISP\_IRQ0ENABLE[x] = 0), the correspondent status (ISP\_IRQ0STATUS [x] = 1) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The PRV\_PCR [1] BUSY status bit is set when the start of frame occurs (if the PRV\_PCR [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The PRV\_PCR [1] BUSY status bit may be polled to determine end-of-frame status.

The PRV\_PCR [31] DRK\_FAIL status bit is set when dark-frame data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

### 1.5.3.4 Register Accessibility During Frame Processing

There are three types of register access in the preview engine.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- PRV\_PCR
- PRV\_RSDR\_ADDR
- PRV\_RADR\_OFFSET
- PRV\_DSDR\_ADDR
- PRV\_DRKF\_OFFSET
- PRV\_WSDR\_ADDR
- PRV\_WADD\_OFFSET

- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.

The busy-writable registers are:

- PRV\_WB\_DGAIN
- PRV\_WBGAIN

- Busy-lock registers:

- All registers EXCEPT the shadow and busy-writable registers belong to this category. Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
- After the PRV\_PCR [1] BUSY bit is reset to 0, busy-lock registers can be written.
- The PRV\_SET\_TBL\_DATA register cannot be read when the preview engine is busy, because this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading preview engine memories.

The ideal procedure for changing the preview engine registers is:

IF (PRV\_PCR [1] BUSY == 0) OR IF  
(EOF interrupt occurs)

DISABLE PREVIEW ENGINE

CHANGE REGISTERS

ENABLE PREVIEW ENGINE

### 1.5.3.5 Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Since the PRV\_PCR register and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

### 1.5.3.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the preview engine. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- A frame can only be read from memory when the SBL read port is affected to the PREVIEW module (ISP\_CTRL [27] SBL\_SHARED\_RPORTA=0)
- The shading compensation feature can only be used when the SBL read port is affected to the PREVIEW module (ISP\_CTRL [28] SBL\_SHARED\_RPORTB=0)
- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- The output width must be less than or equal to 3312.
- The output width must be even.
- Input to the horizontal median filter must be even.
- The horizontal median filter and noise filter should not be enabled for Foveon formatted input.
- Defect correction can only be used when noise filter is enabled
- Input height must be smaller than CCDC output height.
- The input width of the preview engine must be a multiple of the average count multiplied by the least common multiple of the odd distance and even distance of the averager.
  - $(\text{PRV\_HORZ\_INFO [13:0] EPH} - \text{HORZ\_INFO [29:16] SPH} + 1) \text{ MOD } ((1 \text{ PRV\_AVE [1:0] COUNT}) * \text{LeastCommonMultiple}(\text{PRV\_AVE [5:4] ODDDIST}+1, \text{PRV\_AVE [3:2] EVENDIST}+1)) = 0$
- Input width must be at least 4 pixels smaller than CCDC output width:
  - PRV\_HORZ\_INFO [29:16] SPH at least 2 pixels before last pixel from CCDC
  - PRV\_HORZ\_INFO [13:0] EPH at least 2 pixels before last pixel from CCDC

### 1.5.4 Programming the Resizer

This section discusses issues related to software control of the resizer. It lists which registers are required to be programmed in different modes, how to enable and disable the resizer, and how to check the status of the resizer; discusses the different register access types; and enumerates programming constraints.

#### 1.5.4.1 Resizer Hardware Setup/Initialization

This section discusses the configuration of the resizer required before image processing can begin.

##### 1.5.4.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the resizer are reset to their reset values.

##### 1.5.4.1.2 Register Setup

Before to enabling the resizer, the hardware must be correctly configured through register writes. [Table 1-46](#) identifies the register parameters that must be programmed before enabling the resizer.

**Table 1-46. Resizer Required Configuration Parameters**

Function	Configuration Required
Resizer control parameters	RSZ_CNT
I/O sizes	RSZ_OUT_SIZE
	RSZ_IN_START
	RSZ_IN_SIZE

**Table 1-46. Resizer Required Configuration Parameters (continued)**

Function	Configuration Required
Memory addresses	RSZ_SDR_INADD
	RSZ_SDR_INOFF
	RSZ_SDR_OUTADD
	RSZ_SDR_OUTOFF
Filter coefficients	RSZ_HFILT10 to RSZ_HFILT3130
	RSZ_VFILT10 to RSZ_VFILT3130
Edge enhancement	RSZ_YENH [17:16] ALG0

The edge-enhancement function is optional:

- If it is disabled, the rest of the RSZ\_YENH register does not need to be programmed.
- If it is enabled, the edge-enhancement parameters in [Table 1-47](#) must be programmed so that the edge-enhancement function operates correctly.

[Table 1-47](#) can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters must be programmed.

**Table 1-47. Resizer Conditional Configuration Parameters**

Function	Condition	Configuration Required
Edge enhancement	RSZ_YENH [17:16] ALG0 = 0x1 or 0x2	RSZ_YENH [15:12] GAIN
		RSZ_YENH [11:8] SLOP
		RSZ_YENH [7:0] CORE

#### 1.5.4.2 Enable/Disable Hardware

Setting the RSZ\_PCR [0] ENABLE bit to 0x1 enables the resizer. This must be done after all required registers are programmed.

When the input source is memory, the resizer always operates in one-shot mode. In other words, after enabling the resizer, the RSZ\_PCR [0] ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory.

In this mode, fetching and processing of the frame begin immediately on setting the RSZ\_PCR [0] ENABLE bit.

When the input source is the CCDC or preview engine, the Resizer can be configured to operate in either one-shot mode, or continuous mode (RSZ\_PCR [2] ONESHOT). Processing of the frame depends on the timing of the CCDC/Preview. To ensure that data from the CCDC or preview engine is not missed, the resizer must be enabled before to these upstream modules, so it waits for data from the CCDC or the preview engine.

When the resizer is started during an ongoing frame the enable is latched at the end of the frame it was written in.

When the Resizer is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame it was written in.

#### 1.5.4.3 Events and Status Checking

The resizer generates an interrupt event at the end of each frame.

The status of this interrupt can be checked by reading the ISP\_IRQ0STATUS register (or ISP\_IRQ1STATUS). When the read of the register ISP\_IRQ0STATUS occurs (or ISP\_IRQ1STATUS), the register is not automatically reset. To reset the interrupt, a 1 must be written to the RSZ\_DONE\_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the ISP\_IRQ0ENABLE register (or ISP\_IRQ1ENABLE). When a particular event is not enabled (for example ISP\_IRQ0ENABLE[x] = 0), the correspondent status (ISP\_IRQ0STATUS [x] = 1) bit is flagged, if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The RSZ\_PCR [1] BUSY status bit is set when the start of frame occurs (if the RSZ\_PCR [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The RSZ\_PCR [1] BUSY status bit may be polled to determine end-of-frame status in oneshot mode. Figure 1-49 shows the firmware/hardware interaction. Configuration registers and filter coefficients are programmed in-between or before busy periods, before writing ENABLE to 0x1.

**Figure 1-49. Firmware Interactions for Memory-Input Resizing**

**Note:** The SBL\_SDR\_REQ\_EXP [19:10] RSZ\_EXP bit field enables the spreading of non-real time read requests over time. It is useful to avoid overflow situations when the resizer module is programmed to work from memory to memory.

#### 1.5.4.4 Register Accessibility During Frame Processing

There are two types of register access in the resizer.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Note that reads return the most recent write, even though the settings are not used until the next start of frame.  
The shadowed registers are:
  - RSZ\_PCR
  - RSZ\_SDR\_INADD
  - RSZ\_SDR\_INOFF
  - RSZ\_SDR\_OUTADD
  - RSZ\_SDR\_OUTOFF
- Busy-lock registers
  - All registers EXCEPT the shadowed registers belong to this category.
  - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
  - After the RSZ\_PCR [1] BUSY bit is reset to 0, the busy-lock registers can be written.

The ideal procedure for changing the resizer registers is:

```
IF (RSZ_PCR [1] BUSY == 0) OR IF
(EOF interrupt occurs)
    DISABLE RESIZER
    CHANGE REGISTERS
```

## ENABLE RESIZER

### 1.5.4.5 Inter-Frame Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Since the RSZ\_PCR [0] ENABLE bit and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is get latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

---

**Note:** The firmware is responsible for computing and uploading the filter coefficients. If polyphase resampling is used, a different set is required when changing between 4-tap and 7-tap modes, and with different downsampling factors; all upsampling factors can share the same set of coefficients. Do not change any busy-lock registers while the resizer is operating. Specifically, when back-to-back resizes require changes in any busy-lock registers (such as the coefficients, resizing ratios, input and output sizes), users must wait for the first resize to complete. The following section describes some scenarios where this is required.

---

#### 1.5.4.5.1 Multiple Passes for Large Resizing Operations

The resizer supports multiple passes of processing for large resizing operations. "Large" has meanings:

- Wider output than 3312 pixels: This works only in memory input mode. Input can be partitioned into multiple resizer blocks, and each block is separately resized and stitched together. Having input/output memory line offsets, input starting pixel and starting phase are essential to make this work. The basic idea is to begin subsequent slices at exactly where previous images leave off. The starting phase and pixel registers can be programmed to this exact location.
- Larger than 4x upsampling: Resizing can be applied in multiple passes. For example, 10x upsampling can be realized by first a 4x upsampling, then a 2.5x upsampling. The first pass can be performed on-the-fly with the preview engine. The second pass can be performed only with input from memory, and for 10x digital zoom; there is time outside the active picture region to perform the second pass.
- Larger than 4:1 downsampling: Although it is rarely necessary to generate a very small image from a large image, this is supported by the hardware. For example, 10x downsampling can be realized first with 4x downsampling on-the-fly with the preview engine, then 2.5x downsampling in the memory-input path. There may not be much time outside the active data region for the second pass, but since the image is already reduced to 1/16 of its original size, not much time is necessary. Typically, sensor or video input has 10 ~ 20 % of usable vertical blanking.

For all these scenarios, the second pass can be configured and initiated from an interrupt service routine triggered by the resizer end-of-frame interrupt: ISP\_IRQ0ENABLE [24] RSZ\_DONE\_IRQ (or ISP\_IRQ1ENABLE).

#### 1.5.4.5.2 Processing Time Calculation

The time calculated below is the time it takes for all resizes where the input source is memory (second pass when doing a 10x resize in preview mode; in the case of a 10x resize in preview mode, the first pass is hidden behind the time it takes to capture and process the image from the sensor based on cam\_pclk and the number of lines resized).

The following equation can be used to determine the processing time of the resizer when the input is from memory and therefore how much time it takes before it can switch back to preview input mode:

$$\text{Time} = [W \times \text{bytes\_per\_pixel} \times \text{input height}] / \text{CAM\_FCLK}$$

Where:

/\* If the input is YUV422 and horizontal downsampling is performed: \*/

if ((RSZ\_CNT [27] INPTYP == 0) && ((RSZ\_CNT [9:0] HRSZ + 1) > 256))

```
W = average (input_width, output width); /* output width includes extra 4 pixels if edge enhancement is
enabled*/
```

```
else
```

```
W = max(input width, output width); /*output width includes extra 4 pixels if edge enhancement is
enabled*/
```

```
input_width = RSZ_IN_SIZE[12:0]HORZ
```

```
output_width = RSZ_OUT_SIZE[11:0]HORZ
```

```
input_height = RSZ_IN_SIZE[28:16]VERT
```

$$\text{bytes\_per\_pixel} = \begin{cases} 1, & \text{when } \text{RSZ\_CNT}[27]\text{INPTYP} = 1 \text{ (color separate)} \\ 2, & \text{when } \text{RSZ\_CNT}[27]\text{INPTYP} = 0 \text{ (YUV422)} \end{cases}$$

camisp-E097

This time is the baseline steady state calculation of the hardware and does not include the time it takes for the hardware to fetch the first input and fill the pipeline. It also does not include the time spent from the last output from the resizer to get back to memory when the resizer interrupt occurs.

However, these beginning and ending times are relatively negligible.

Depending on real-time constraints, this processing time may be much faster than is required. (data fetches can be delayed from memory to free more bandwidth for use by other system peripherals; see [Section 1.5.7.5.2, Input from Memory](#).)

#### 1.5.4.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the resizer. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- Vertical and horizontal resize ratio values must be within the following range: [64..1024].
- Output width:
  - Must be within the maximum limit:
    - width 3312 (if vertical resize value is in range:  $(\text{RSZ\_CNT}[19:10] \text{ VRSZ} + 1) = [64..512]$ )
    - width 1650 (if vertical resize value is in range:  $(\text{RSZ\_CNT}[19:10] \text{ VRSZ} + 1) = [513..1024]$ )
  - Must be even
  - Must be a multiple of 16 bytes (for vertical upsizing)
- When input is from preview engine/CCDC:
  - The input height and width must be  $\leq$  the output of the preview engine/CCDC.
  - The input address and offset must be zero.
  - The input can not be color-separated data.
- If the source is memory:
  - The vertical start pixel must be zero.
  - The horizontal start pixel must be within the range: 0:15 for color interleaved, 0:31 for color separate data.
  - The memory output line offset and address must be on 32-byte boundaries.
- Input height and width MUST adhere to the equations in [Table 1-48](#).

**Table 1-48. How to Set Input Height and Width**

	8-phase, 4-tap mode	4-phase, 7-tap mode
RSZ_IN_SIZE [12:0] HORZ	$(32 * \text{sph} + (\text{ow} - 1) * \text{hrs} + 16) \gg 8 + 7$	$(64 * \text{sph} + (\text{ow} - 1) * \text{hrs} + 32) \gg 8 + 7$
RSZ_IN_SIZE [28:16] VERT	$(32 * \text{spv} + (\text{oh} - 1) * \text{vrs} + 16) \gg 8 + 4$	$(64 * \text{spv} + (\text{oh} - 1) * \text{vrs} + 32) \gg 8 + 7$

Where:

- sph = Start phase horizontal (RSZ\_CNT [22:20] HSTPH)
- spv = Start phase vertical (RSZ\_CNT [25:23] VSTPH)
- ow = Output width (RSZ\_OUT\_SIZE [11:0] HORZ + extra)
- oh = Output height (RSZ\_OUT\_SIZE [27:16] VERT)
- hrsz = Horizontal resize value (RSZ\_CNT [9:0] HRSZ + 1)
- vrsz = Vertical resize value (RSZ\_CNT [19:10] VRSZ + 1)
- extra = 0 when RSZ\_YENH [17:16] ALGO = 0 (edge enhancement disabled)
- extra = 4 when RSZ\_YENH [17:16] ALGO != 0 (edge enhancement enabled)

**Note:** Normally, (for example, for a QVGA display or encoded PAL video), the output size, not the input size, matters. The image provided by preview/CCDC/memory must have an adequate output size: at least RSZ\_IN\_SIZE[12:0] HORZ x RSZ\_IN\_SIZE [28:16] VERT. If the image is bigger, the resizer can crop extra pixels.

The phase is usually computed to keep the center of the image at the same location. This permits a natural-looking continuous digital zoom.

For this reason, [Table 1-48](#) explains how to compute RSZ\_IN\_SIZE [12:0] HORZ , RSZ\_IN\_SIZE [28:16] VERT, not how to compute the output size.

## 1.5.5 Programming the H3A

This section discusses issues related to software control of the H3A module. It lists which registers are required to be programmed in different modes, how to enable and disable the H3A, and how to check the status of the H3A; discusses the different register access types; and enumerates programming constraints.

### 1.5.5.1 Hardware Setup/Initialization

This section discusses the configuration of the H3A required before image processing can begin.

#### 1.5.5.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the H3A are reset (set to their reset values).

#### 1.5.5.1.2 Register Setup

For register configuration, the AF engine and the AEW engine of the H3A can be independently be configured. Because there are separate enable bits for each engine, so this section discusses the AF engine and the AEW engine separately.

##### 1.5.5.1.2.1 AF Engine

Before enabling the AF engine, the hardware must be correctly configured through register writes. [Table 1-49](#) identifies the register parameters that must be programmed before enabling the AF engine of the H3A.

**Table 1-49. AF Engine Required Configuration Parameters**

Function	Configuration Required
AF optional preprocessing	H3A_PCR [2] AF_MED_EN
	H3A_PCR [1] AF_ALAW_EN

**Table 1-49. AF Engine Required Configuration Parameters (continued)**

Function	Configuration Required
AF mode configuration	H3A_PCR [13:11] RGBPOS H3A_PCR [14] FVMODE
Paxel start and size information	H3A_AFPAX1 H3A_AFPAX2 H3A_AFPAXSTART H3A_AFIIRSH
Memory address	H3A_AFBUFST
Filter coefficients	H3A_AFCOEF010 to H3A_AFCOEF1010

The horizontal median filter function is optional.

If it is disabled, the H3A\_PCR [10:3] MED\_TH does not need to be programmed.

However, if it is enabled, the H3A\_PCR [10:3] MED\_TH parameter must be programmed so that the horizontal median filter function operates correctly.

[Table 1-50](#) can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters must be programmed

**Table 1-50. AF Engine Conditional Configuration Parameters**

Function	Condition	Configuration Required
Horizontal median filter	H3A_PCR [2] AF_MED_EN	H3A_PCR [10:3] MED_TH

#### 1.5.5.1.2.2 AEW Engine

Before enabling the AEW engine, the hardware must be correctly configured through register writes.

[Table 1-51](#) identifies the register parameters that must be programmed before enabling the AEW engine of the H3A.

**Table 1-51. AEW Engine Required Configuration Parameters**

Function	Configuration Required
AEW optional preprocessing	H3A_PCR [17] AEW_ALAW_EN
Saturation limit	H3A_PCR [31:22] AVE2LMT
Window start and size information	H3A_AEWWIN1 H3A_AEWINSTART H3A_AEWINBLK H3A_AEWSUBWIN
Memory address	H3A_AEWBUFST

#### 1.5.5.2 Enable/Disable Hardware

Setting the H3A\_PCR [0] AF\_EN bit enables the AF engine, and the H3A\_PCR [16] AEW\_EN bit enables the AEW engine. This should be done after all required registers are programmed.

The H3A always operates in continuous mode. Since the input to the H3A module is the video-port interface of the CCDC, processing of the frame depends on the timing signals from the CCDC. To ensure that data from the CCDC is not missed, the H3A should be enabled before the CCDC so that it waits for CCDC data.

The AF engine or the AEW engine can be disabled by clearing the H3A\_PCR [0] AF\_EN or H3A\_PCR [16] AEW\_EN bit, respectively, during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

### 1.5.5.3 Event and Status Checking

Both the AF engine and the AEW engine generate an interrupt at the end of processing each frame. These interrupt events can be sent to CAM\_IRQ0 or CAM\_IRQ1 by setting the H3A\_AWB\_DONE\_IRQ or H3A\_AF\_DONE\_IRQ bits in the ISP\_IRQ0ENABLE enable register (or ISP\_IRQ1ENABLE).

The status of these interrupts can be checked by reading the ISP\_IRQ0STATUS register (or ISP\_IRQ1STATUS). When the read of the register ISP\_IRQ0STATUS occurs (or ISP\_IRQ1STATUS), the register is not automatically reset. To reset the interrupt, a 1 must be written to the corresponding bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the ISP\_IRQ0ENABLE register (or ISP\_IRQ1ENABLE). When a particular event is not enabled (for example ISP\_IRQ0ENABLE[x] = 0), the correspondent status (ISP\_IRQ0STATUS [x] = 1) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

### 1.5.5.4 Register Accessibility During Frame Processing

There are two types of register access in the H3A module:

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.  
The shadowed registers are:
  - H3A\_PCR
  - H3A\_AFBUFST
  - H3A\_AEWBUFST
- Busy-lock registers:
  - All registers EXCEPT the shadowed registers belong to this category.
  - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
  - After the busy bit in the PCR register is reset to 0, the busy-lock registers can be written (H3A\_PCR [15] BUSYAF for AF registers and H3A\_PCR [18] BUSYAEAWB for AE/AWB registers).

The ideal procedure for changing the H3A registers is:

```
IF (H3A_PCR [15] BUSYAF == 0 OR H3A_PCR [18] BUSYAEAWB == 0) OR IF (EOF interrupt occurs)
    DISABLE AF or AE/AWB
    CHANGE REGISTERS AF or AE/AWB
    ENABLE AF or AE/AWB
```

### 1.5.5.5 Interframe Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Since the H3A\_PCR and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

### 1.5.5.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the H3A. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The H3A should not be enabled for Foveon formatted input.
- The output addresses must be on 64-byte boundaries.
- AF Engine:
  - The paxel horizontal start value must be greater than or equal to the IIR horizontal start position.
  - The width and height of the paxels must be even numbers.
  - The minimum width of the autofocus paxel must be 6 pixels.
  - Paxels cannot overlap the last pixel in a line.
  - Paxels must be adjacent to one another.
- AEW Engine:
  - The width and height of the windows must be even numbers.
  - Subsampling windows can only start on even numbers.
  - The minimum width of the AE/AWB windows is 6 pixels.

## 1.5.6 Programming the Histogram

This section discusses issues related to software control of the histogram module. It lists which registers are required to be programmed in different modes, how to enable and disable the histogram, and how to check the status of the histogram; discusses the different register access types; and enumerates programming constraints.

### 1.5.6.1 Hardware Setup/Initialization

This section discusses the configuration of the histogram required before image processing can begin.

#### 1.5.6.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the histogram are reset to their reset values. However, since the histogram output memory is stored in internal memory, its contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of this memory are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of this memory remain the same as before the reset.

#### 1.5.6.1.2 Reset of Histogram Output Memory

Clear the output memory before enabling the histogram. This can be done two ways:

- Writing zeros to the memory through software
- If the HIST\_CNT [7] CLR bit is set, reading the memory causes it to be reset after the read.

Reads and writes to the output memory are blocked when the HIST\_PCR [1] BUSY bit is 1.

#### 1.5.6.1.3 Register Setup

Before enabling the histogram module, the hardware must be correctly configured through register writes. [Table 1-52](#) identifies the register parameters that must be programmed before enabling the histogram.

**Table 1-52. Histogram Required Configuration Parameters**

Function	Configuration Required
Histogram Control Bits	HIST_CNT [3] SOURCE HIST_CNT[6] CFA HIST_CNT [5:4] BINS HIST_CNT [2:0] SHIFT HIST_CNT [7] CLR
White Balance Gain	HIST_WB_GAIN
Region n Size and position (n = 0)	HIST_Rn_HORZ HIST_Rn_VERT

Table 1-53 can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters should be programmed

**Table 1-53. Histogram Conditional Configuration Parameters**

Function	Condition	Configuration Required
Input from memory	HIST_CNT [3] SOURCE = 0x1	HIST_CNT [8] DATSIZ HIST_RADD HIST_RADD_OFF HIST_H_V_INFO
Less than 256 bins	HIST_CNT [5:4] BINS 3	HIST_Rn_HORZ (n = 1) HIST_Rn_VERT (n = 1)
Less than 128 bins	HIST_CNT [5:4] BINS 2	HIST_Rn_HORZ (n = 2) HIST_Rn_VERT (n = 2) HIST_Rn_HORZ (n = 3) HIST_Rn_VERT (n = 3)

### 1.5.6.2 Enable/Disable Hardware

Setting the HIST\_PCR [0] ENABLE bit enables the histogram module. This must be done after all required registers are programmed and the output memory has been cleared.

When the input source is the memory, the histogram module always operates in one-shot mode. In other words, after enabling the histogram, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCDC, the histogram always operates in continuous mode. Processing of the frame depends on the timing of the CCDC. To ensure that data from the CCDC is not missed, the histogram must be enabled before CCDC so it waits for CCDC data..

When the histogram is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

### 1.5.6.3 Event and Status Checking

The histogram generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the ISP\_IRQ0STATUS register (or ISP\_IRQ1STATUS). When the read of the register ISP\_IRQ0STATUS occurs (or ISP\_IRQ1STATUS), the register is not automatically reset. To reset the interrupt, a 1 must be written to the HIST\_DONE\_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the ISP\_IRQ0ENABLE register (or ISP\_IRQ1ENABLE). When a particular event is not enabled (for example ISP\_IRQ0ENABLE[x] = 0), the corresponding status (ISP\_IRQ0STATUS [x] = 1) bit is flagged if the corresponding event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The HIST\_PCR [1] BUSY status bit is set when the start of frame occurs (if the HIST\_PCR [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The HIST\_PCR [1] BUSY status bit may be polled to determine the end-of-frame status.

#### 1.5.6.4 Register Accessibility During Frame Processing

There are two types of register access in the histogram module.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.  
The shadowed registers are:
  - HIST\_PCR
  - HIST\_RADD
  - HIST\_RADD\_OFF
- Busy-lock registers
  - All registers EXCEPT the shadowed registers belong to this category.
  - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
  - After the HIST\_PCR [1] BUSY bit is reset to 0, the busy-lock registers can be written.
  - The HIST\_DATA register cannot be read when the histogram is busy, because since this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading the histogram memory.

The ideal procedure for changing the histogram registers is:

```
IF (HIST_PCR [1] BUSY == 0) OR IF (EOF interrupt occurs)
    DISABLE HISTOGRAM
    CHANGE REGISTERS
    ENABLE HISTOGRAM
```

#### 1.5.6.5 Interframe Operations

Between frames read from memory, it may be necessary to modify the input memory pointers before processing the next frame. Since the H3A\_PCR and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

If continuous frames are processed without clearing the histogram output memory, the bin counters contain the counts of however many images are processed since they were last cleared. To read the bin counters for each frame, the bin counters must be read after each frame is completed, but before the next frame begins (since the counters cannot be read while the HIST\_PCR [1] BUSY bit is 1).

If the input source is memory (one-shot mode), the HIST\_PCR [0] ENABLE bit must be set once for the frame, and after the frame is completed, the bin counters can be read/cleared before enabling the next frame.

When the input source is the video-port interface of the CCDC (continuous mode), the HIST\_PCR [0] ENABLE bit must be set to enable processing of the frame, and cleared after the frame processing begins (the disable is latched in at the end of the frame). This procedure allows only one frame to be processed. After the frame is completed, the bin counters can be read/cleared before enabling the histogram for the next frame.

#### 1.5.6.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the histogram. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The input address and line offset must be on 32-byte boundaries.
- A region dimension of 1 (horizontal or vertical or both) is not allowed.

### 1.5.7 Programming the Central-Resource SBL

This section discusses issues related to the software control of the central-resource SBL. It lists which registers are required to be programmed in different modes, describes how to check the status of the central resource SBL overflow bits, and enumerates programming constraints.

The central-resource SBL controls data interactions between the camera ISP modules and the interface to memory. A small number of registers configure maximum data-read bandwidth in memory-to-memory operations.

#### 1.5.7.1 Hardware Setup/Initialization

This section discusses the configuration of the central-resource SBL required before image processing can begin.

##### 1.5.7.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the SBL are reset to their reset values.

##### 1.5.7.1.2 Register Setup

Before enabling any of the camera ISP modules, the hardware must be correctly configured through register writes to the camera ISP registers. If the preview engine, resizer, or the histogram is reading from memory, the SBL\_SDR\_REQ\_EXP register must be programmed. The values programmed in each of the three fields (PRV\_EXP, RSZ\_EXP, HIST\_EXP) determines the number of clock cycles required to allow two consecutive read requests from the module.

#### 1.5.7.2 Enable/Disable Hardware

The central-resource SBL functionality is always enabled, unless the PRCM idles the clocks to the camera ISP.

#### 1.5.7.3 Event and Status Checking

The SBL generates one interrupt for the write buffer overflow events listed below. Software must check which overflow event has raised the interrupt request, by reading the SBL\_PCR register.

See [Table 1-54](#).

**Table 1-54. SBL Write-Buffer Overflow Events**

Bit	Event Description
SBL_PCR [24] CCDCPRV_2_RSZ_OVF	CCDC/PREVIEW to RESIZER input overflow This bit is set if the RESIZER input source is sent to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of > 4x is required per frame. Therefore, the RESIZER must operate in two passes. In the first pass, the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should start only after the second pass on the previous frame is complete. This bit indicates the failure status.
SBL_PCR [23] CCDC_WBL_OVF	CCDC write-buffer memory overflow
SBL_PCR [22] PRV_WBL_OVF	PREVIEW write-buffer memory overflow
SBL_PCR [21] RSZ1_WBL_OVF	RESIZER line 1 write-buffer memory overflow
SBL_PCR [20] RSZ2_WBL_OVF	RESIZER line 2 write-buffer memory overflow
SBL_PCR [19] RSZ3_WBL_OVF	RESIZER line 3 write-buffer memory overflow
SBL_PCR [18] RSZ4_WBL_OVF	RESIZER line 4 write-buffer memory overflow
SBL_PCR [17] H3A_AF_WBL_OVF	H3A AF write-buffer memory overflow
SBL_PCR [16] H3A_AEAWB_WBL_OVF	H3A AE/AWB write-buffer memory overflow

The status of this interrupt can be checked by reading the ISP\_IRQ0STATUS register (or ISP\_IRQ1STATUS). When the read of the register ISP\_IRQ0STATUS occurs (or ISP\_IRQ1STATUS), the register is not automatically reset. To reset the interrupt, a 1 must be written:

- To the corresponding bit(s) in the SBL\_PCR registers
- To the OVF\_IRQ bit in the ISP\_IRQ0STATUS register (or ISP\_IRQ1STATUS)

Each event that generates an interrupt can be individually mapped to ARM or DSP using the ISP\_IRQ0ENABLE register (or ISP\_IRQ1ENABLE). When a particular event is not enabled (for example ISP\_IRQ0ENABLE[x] = 0), the correspondent status (ISP\_IRQ0STATUS [x] = 1) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The SBL flags no read buffer logic underflow events. These are signaled by the reading module.

[Table 1-55](#) lists the read port and corresponding events if they exist.

**Table 1-55. SBL Read-Buffer Underflow Events**

Read port	Description
CCDC faulty pixel	When faulty-pixel correction is used, the pixel frequency is imposed by the camera clock. This imposes read-time constraints to the faulty-pixel table read. When the table read was too slow, the CCDC_FPC [16] FPERR bit is set to 1 and no more faulty pixels are processed for that frame. This error generates an interrupt that can be mapped to DSP or ARM by setting the CCDC_ERR_IRQ bit in the ISP_IRQ0ENABLE register (or ISP_IRQ1ENABLE). To clear this interrupt, clear the CCDC_FPC [16] FPERR bit before clearing the ISP_IRQ0STATUS [11] CCDC_ERR_IRQ bit (or ISP_IRQ1STATUS).
CCDC lens-shading compensation	There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, then the CCDC_LSC_PREFETCH_ERROR event is triggered and an interrupt generated.
Preview dark frame	There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the PRV_PCR [31] DRK_FAIL status bit is set to indicate a fail. No interrupt is generated by this event.

**Table 1-55. SBL Read-Buffer Underflow Events (continued)**

Read port	Description
Preview image from memory	No error can occur on this port because the preview module stops processing when no image data is ready.
Resizer image from memory	No error can occur on this port because the resizer module stops processing when no image data is ready.
Histogram image from memory	No error can occur on this port because the histogram module stops processing when no image data is ready.

### 1.5.7.4 Register Accessibility During Frame Processing

The central resource SBL registers are all busy-writable registers.

- Busy-writable registers
  - These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.

### 1.5.7.5 Camera ISP Bandwidth Adjustments

For memory-to-memory operation, the camera ISP processes data at the highest possible data rate. If this processing returns results long before real-time deadlines, the performance of other peripherals in the system may be negatively affected. The camera ISP offers two kinds of adjustments that can slow down data processing in this situation. One can be made when the sensor input to the CCDC is the input source, and the other can be made when the memory is the source of the input image.

#### 1.5.7.5.1 Input From CCDC Video-Port Interface

The video-port interface delivers data at a rate independent of the pixel clock when the data reformatter is enabled. By default, this rate is set to 83 MHz, which is fast enough to support a parallel interface clock of 75 MHz. When the pixel clock is at a lower frequency, it is unnecessary for the video-port interface to operate at such a high frequency. The CCDC\_FMTCFG [18:16] VPIF\_FRQ field of the CCDC can be programmed to reduce the rate at which the video port delivers new data to the other modules (Preview, H3A, and histogram). In effect, this register indirectly controls the output bandwidth of the preview engine, resizer, and H3A. Depending on the input sensor clock, Users can set this field appropriately and balance the bandwidth requirements to memory. Figure 1-50 demonstrates how this register can expand processing time per line for lower PCLK frequencies.

**Figure 1-50. Video-Port Interface Bandwidth Balancing**

camisp-091

### 1.5.7.5.2 Input From Memory

When the input image is from memory, data is fetched from memory and processed at a steady state rate of 166 MB/sec. Depending on the image size and real-time deadline for each frame, this may be much faster than necessary. Such activity can also starve other processes in the system. Internally, when a CAMERA ISP module receives input from memory, the CAMERA ISP makes a read request to the L3 interconnect whenever there is available memory in its internal buffers. The SBL\_SDR\_REQ\_EXP register can be programmed to control the rate at which a camera ISP module (Preview, resizer, or histogram) reads the input frame from memory. This indirectly controls the output bandwidth of the preview engine and resizer. Depending on the size of the images and the real-time deadlines, users can set this field appropriately and balance the bandwidth requirements to memory.

The minimum number of cycles (L3) in between read requests used to program the SBL\_SDR\_REQ\_EXP register can be determined based on the frame size and real-time requirement using the following equation:

$$\text{Number of cycles/request} = (\text{DMA cycles/frame}) / (\text{DMA read requests/frame})$$

In the previous equation, (DMA cycles/frame) is based on the real-time requirement. For example, if the real-time requirement is a frame rate of 1/30 sec and the L3 clock is 166 MHz, this can be calculated as:

$$(\text{DMA cycles/frame}) = \text{L3 clock} * \text{frame rate} = 166 \text{ MHz} * 1/30 = 5.53\text{M cycles}$$

The (DMA read requests/frame) is based on the frame size and the alignment in memory. Assuming a VGA (640x480) frame size and optimal alignment conditions:

$$(\text{DMA read requests/frame}) = \text{Transfers per line} * \text{number of lines} = 640 \text{ pix/line} * 2 \text{ bytes/pix} / 256 \text{ bytes/xfer} * 480 \text{ lines} = 2400 \text{ requests/frame}$$

In this example, the final equation can now be solved:

$$\text{Number of cycles/request} = 5.53\text{M cyles} / 2400 \text{ requests} = 2306 \text{ cycles/request}$$

Figure 1-51 demonstrates how this register can expand processing time for lower real-time requirements.

**Figure 1-51. Memory Read Bandwidth Balancing**

The maximum values that can be written to the SBL\_SDR\_REQ\_EXP register for the different read requestors is 1023. For the histogram and preview engine, this should be sufficient for the typical size of RAW data frames. However, because the resizer can read a variety of video frame sizes, the field for the resizer is internally multiplied by 1024. Therefore, for this example, the SBL\_SDR\_REQ\_EXP [19:10] RESZ\_EXP bit field can be programmed to  $\text{FLOOR}(2306/1024) = 3$ . The previous equations provide an estimate or a starting point for programming this register. Depending on the system loads and available bandwidth, it may be necessary to reduce this number to compensate for a heavily loaded system.

**Note:** The granularity for the resizer and preview is 1024, and for HIST it is 32.

## 1.5.8 Programming the Circular Buffer (CBUFF)

### 1.5.8.1 Hardware Setup/Initialization

This section discusses the configuration of the circular buffer required before address translation can begin.

### 1.5.8.2 Reset Behavior

Upon hardware reset of the circular buffer, all of the registers in the circular buffer are reset to their reset values.

### 1.5.8.3 Register Setup

All registers of the circular buffer to be used (CBUFFx, x=0 or 1) have to be initialized for correct operation.

The CBUFFx\_START and CBUFFx\_END register define the virtual address range managed by the circular buffer. It usually corresponds to the address region where one image frame is written by the camera ISP.

The window count and size are set through the CBUFFx\_CTRL [9:8] WCOUNT and CBUFFx\_WINDOWSIZE registers. The window size usually depends on the utilization of the buffer. 8 or 16 video lines correspond to a current size for JPEG video compression. A higher window count provides better latency related overflow protection.

When the camera ISP accesses data in an incremental addressing scheme, the next window is never used. In this case the overflow event generation, when the processor window falls into the "next window", can be disabled by setting the CBUFFx\_CTRL [3] ALLOW\_NW\_EQ\_CPUW flag.

When the 2D addressing capability isn't used the CBUFFx\_THRESHOLD register is set to the window size. Otherwise it is set to a smaller value depending on the buffer organization. For example, when each window corresponds to 8 lines by 4096 pixel but the camera ISP only send lines of 2560 pixels the CBUFFx\_WINDOWSIZE=8\*4096 and CBUFFx\_THRESHOLD=8\*2560.

When the register setup is completed the module is enabled using the CBUFFx\_CTRL [0] EN bit.

It can be disabled by clearing the CBUFFx\_CTRL [0] EN bit. This must only be done when there are no more outstanding requests to the virtual space managed by CBUFFx. All internal FSMs and counters of the circular buffer are reset when it is disabled. Pending interrupts are not affected.

### 1.5.8.4 Event and status Checking

#### 1.5.8.4.1 Interrupts

All events generated by the circular buffer are mapped to an unique event at camera ISP level: CBUFF\_IRQ,

The CBUFF module event can be mapped to the MPU SS or to the IVA SS.

The CBUFF\_IRQ bit in the ISP\_IRQ0ENABLE [21] CBUFF\_IRQ register control whether the CBUFF module event triggers an interrupt to the MPU SS. The CBUFF\_IRQ bit in the ISP\_IRQ0ENABLE [21] CBUFF\_IRQ register control whether the CBUFF module event triggers an interrupt to the IVA2.2 SS.

When an event has been triggered the ISP\_IRQ0STATUS [21] CBUFF\_IRQ bit is set (or ISP\_IRQ1STATUS). SW must then read the CBUFF\_IRQSTATUS register to know which circular buffer event has triggered the interrupt. SW must clear the event first in the circular buffer module by writing 1 to the proper bit in CBUFF\_IRQSTATUS register and then clear the event at camera ISP level by writing 1 to the ISP\_IRQ0STATUS [21] CBUFF\_IRQ bit (or ISP\_IRQ1STATUS). If another event is pending at circular buffer level, the CBUFF\_IRQ interrupt is triggered again.

#### 1.5.8.4.2 Status Checking

The event status can be checked through the CBUFFx\_READY\_IRQ, CBUFFx\_INVALID\_IRQ and CBUFFx\_OVR\_IRQ bits in the CBUFF\_IRQSTATUS registers.

In addition to those status bits the circular buffer module provides read only access to the "current window", "next window" and "CPU windows" indexes through the CBUFFx\_STATUS register. The "CPU window" index can for example be used by the processor to compute the address of the physical buffer. Those indexes can also be used to evaluate latency margins.

#### 1.5.8.5 Register Accessibility During Frame Processing

All registers are Busy-writeable registers. These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantaneously. However the module behavior is unpredictable when registers are changed during processing.

For correct operation software must follow the following steps:

- Disable all accesses to the virtual space managed by CBUFFx. For example when the circular buffer relocates data provided by the CCDC module SW must disable the CCDC module and check SBL status registers to make sure there are no more outstanding transactions.
- Disable circular buffer x by clearing the CBUFFx\_CTRL [0] ENABLE bit.
- Change the configuration.
- Re-enable CBUFFx by setting the CBUFFx\_CTRL [0] ENABLE bit.

#### 1.5.8.6 Operations

A CBUFFx\_READY\_IRQ event is generated each time processor can read data from the circular buffer. Processor can clear the event when it starts processing the data to avoid masking of other events. Processor can keep trace of the location on the data internally or use the circular buffer registers to compute it.

The formula used is:

$$ADDR = CBUFFx\_STATUS [3:0] CPUW \times CBUFFx\_WINDOWSIZE + CBUFFx\_START$$

When processor is done with processing, it must free the buffer by setting the CBUFFx\_CTRL [2] DONE bit. Otherwise an overflow event may occur.

Note that the circular buffer does not keep trace of end of frame events. They have to be managed by the processor using the end of frame event of the module that writes into the circular buffer. At the end of the frame there may remain data in the "current write" and "next write" windows. For example, when the window size is set to 8 lines and the image size is 20 lines only 2 window ready events are generated for a linear addressing scheme. The remaining 4 lines can be read after the end of frame event.

No automatic reset of the CBUFF FSM occurs at the end of the camera ISP frame. Software must reset the CBUFF by clearing the CBUFFx\_CTRL [0] ENABLE bit when the frame has been completely processed. A new frame can only start when CBUFFx\_CTRL [0] ENABLE has been set.

## 1.6 Camera ISP Registers

**Table 1-56. Physical Addresses of CAMERA\_ISP**

Module Name	Base address (hex)	Size
ISP	0x480B C000	512 bytes
ISP_CBUFF	0x480B C100	256 bytes
ISP_CCDC	0x480B C600	512 bytes
ISP_HIST	0x480B CA00	512 bytes
ISP_H3A	0x480B CC00	512 bytes
ISP_PREVIEW	0x480B CE00	512 bytes
ISP_RESIZER	0x480B D000	512 bytes
ISP_SBL	0x480B D200	512 bytes

### 1.6.1 Register Mapping Summary

**Table 1-57. ISP Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address	Section
ISP_SYSCONFIG	RW	32	0x0000 0004	0x480B C004	<a href="#">Section 1.6.2.1</a>

## 1.6.2 ISP Register Descriptions

### 1.6.2.1 ISP\_SYSCONFIG

**Table 1-65. ISP\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0004																<b>Instance</b>																ISP															
<b>Physical Address</b>	0x480B C004																																															
<b>Description</b>	ISP SYSTEM CONFIGURATION REGISTER																																															
<b>Type</b>	RW																																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																	
RESERVED																MIDLE_MODE		RESERVED														SOFT_RESET	AUTO_IDLE															
<b>Bits</b>	<b>Field Name</b>																<b>Description</b>																<b>Type</b>				<b>Reset</b>											
31:14	RESERVED																Write 0s for future compatibility. Reads returns 0.																RW				0x00000											
13:12	MIDLE_MODE																Master interface power management, handshake protocol.  0x0: Force-standby: the hardware signal is only asserted to the power and reset clock manager when the module is disabled.  0x1: No-standby: the hardware signal is never asserted to the power and reset clock manager.  0x2: Smart-standby: the hardware signal is asserted to the power and reset clock manager based on the internal activity of the module. The ISP clocks are not disabled during smart standby.																RW				0x0											
11:2	RESERVED																Write 0s for future compatibility. Reads returns 0.																RW				0x000											

Bits	Field Name	Description	Type	Reset
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger the module reset. The bit is automatically reset by the HW. During reads return 0.  0x0: Normal mode. 0x1: The module is reset.	RW	0x0
0	AUTO_IDLE	Internal interface clock gating strategy  0x0: interface clock is free running 0x1: Automatic interface clock gating strategy is applied based on the Interconnect interface activity.	RW	0x1

### 1.6.2.2 ISP\_SYSSTATUS

### Table 1-66. ISP\_SYSSTATUS

<b>Address Offset</b>	0x0000 0008																																
<b>Physical Address</b>	0x480B C008																<b>Instance</b>	ISP															
<b>Description</b>	ISP SYSTEM STATUS REGISTER																																
<b>Type</b>	R																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED																															RESET_DONE		

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x00000000
0	RESET_DONE	Internal reset monitoring 0x0: Internal module reset is ongoing. 0x1: Reset completed.	R	0x1

### 1.6.2.3 ISP IRQ0ENABLE

### Table 1-67. ISP\_IRQ0ENABLE

<b>Address Offset</b>	0x0000 000C		
<b>Physical Address</b>	0x480B C00C	<b>Instance</b>	ISP
<b>Description</b>	INTERRUPT ENABLE REGISTER TO MCU. IRQ0 STATUS LINE. The same events are mapped in IRQ1. However, one event should be mapped to only one target.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_VS_IRQ	SEC_ERR_IRQ	OCP_ERR_IRQ	MMU_ERR_IRQ	RESERVED	OVF_IRQ	RSZ_DONE_IRQ	RESERVED	RESERVED	CBUFF_IRQ	PRV_DONE_IRQ	CCDC_LSC_PREFETCH_ERROR	CCDC_LSC_PREFETCH_COMPLETED	CCDC_LSC_DONE	HIST_DONE_IRQ	RESERVED	RESERVED	H3A_AWB_DONE_IRQ	H3A_AF_DONE_IRQ	CCDC_ERR_IRQ	CCDC_VD2_IRQ	CCDC_VD1_IRQ	CCDC_VD0_IRQ	RESERVED								

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection is chosen with the ISP_CTRL.SYNC_DETECT bit field.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
30	SEC_ERR_IRQ	Security error event. The event is triggered when a privilege violation error occurs.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
29	OCP_ERR_IRQ	ISP Interconnect error. This event is triggered when an Interconnect error occurs: SResp = ERR. The cause may be a security violation.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
28	MMU_ERR_IRQ	MMU error.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
27:26	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
25	OVF_IRQ	Central Resource SBL overflow This event is triggered when one of the buffer in the central resource SBL overflows.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
23:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
21	CBUFF_IRQ	Circular buffer interrupt  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Bits	Field Name	Description	Type	Reset
20	PRV_DONE_IRQ	PREVIEW module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read too slowly from SDRAM. When this event is pending the module goes into transparent mode (output=input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
16	HIST_DONE_IRQ	HIST module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
10	CCDC_VD2_IRQ	CCDC module - programmable event 2  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
8	CCDC_VD0_IRQ	CCDC module - programmable event 0.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:0	RESERVED	Reserved bit field. Write the reset value.	RW	0x0

### 1.6.2.4 ISP\_IRQ0STATUS

**Table 1-68. ISP\_IRQ0STATUS**

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	ISP
<b>Physical Address</b>	0x480B C010		
<b>Description</b>	INTERRUPT STATUS REGISTER TO MCU. IRQ0 STATUS LINE.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_VS_IRQ	SEC_ERR_IRQ	OCP_ERR_IRQ	MMU_ERR_IRQ	RESERVED		OVF_IRQ	RSZ_DONE_IRQ	RESERVED		CBUFF_IRQ	PRV_DONE_IRQ	CCDC_LSC_PREFETCH_ERROR	CCDC_LSC_PREFETCH_COMPLETED	CCDC_LSC_DONE	HIST_DONE_IRQ	RESERVED		H3A_AWB_DONE_IRQ	H3A_AF_DONE_IRQ	CCDC_ERR_IRQ	CCDC_VD2_IRQ	CCDC_VD1_IRQ	CCDC_VD0_IRQ	RESERVED							

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event READS: 0: event is false- 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
30	SEC_ERR_IRQ	Security error READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
29	OCP_ERR_IRQ	ISP Interconnect error. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
28	MMU_ERR_IRQ	MMU error. If event is true, one needs to read the MMU_IRQSTATUS register to know the event source. Write in MMU_IRQSTATUS to clear the bit. READS: 0: event is false 1: event is true	R/W/1to Clr	0x0
27:26	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0

Bits	Field Name	Description	Type	Reset
25	OVF_IRQ	Central Resource SBL overflow If event is true, one needs to check the SBL_PCR register to know the source. One needs to clear the SBL_PCR register first before clearing this bit. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	R/W/1to Clr	0x0
23:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0
21	CBUFF_IRQ	A circular buffer event is pending. Check submodule's interrupt status register. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
20	PRV_DONE_IRQ	PREVIEW module - processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read to slowly from SDRAM. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
16	HIST_DONE_IRQ	HIST module - processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0

Bits	Field Name	Description	Type	Reset
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow If event is true, one needs to clear the CCDC_FPC.FPERR bit first before clearing this bit. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
8	CCDC_VD0_IRQ	CCDC module - programmable event 0. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
7:0	RESERVED	Reserved bit field. Write the reset value.	R/W/1to Clr	0x0

### 1.6.2.5 ISP\_IRQ1ENABLE

**Table 1-69. ISP\_IRQ1ENABLE**

Address Offset		0x0000 0014																Instance		ISP															
Physical Address		0x480B C014																																	
Description		INTERRUPT ENABLE REGISTER TO DSP. IRQ1 STATUS LINE. The same events are mapped in IRQ0. However, one event should be mapped to only one target.																																	
Type		RW																																	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_VS_IRQ	SEC_ERR_IRQ	OCP_ERR_IRQ	MMU_ERR_IRQ	RESERVED		OVF_IRQ	RSZ_DONE_IRQ	RESERVED	CBUFF_IRQ	PRV_DONE_IRQ	CCDC_LSC_PREFETCH_ERROR	CCDC_LSC_PREFETCH_COMPLETED	CCDC_LSC_DONE	HIST_DONE_IRQ	RESERVED	H3A_AWB_DONE_IRQ	H3A_AF_DONE_IRQ	CCDC_ERR_IRQ	CCDC_VD2_IRQ	CCDC_VD1_IRQ	CCDC_VD0_IRQ	RESERVED									

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection is chosen with the ISP_CTRL.SYNC_DTECT bit field.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
30	SEC_ERR_IRQ	Security error event. The event is triggered when a privilege violation error occurs.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
29	OCP_ERR_IRQ	ISP Interconnect error. This event is triggered when an Interconnect error occurs: SResp = ERR. The cause may be a security violation.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
28	MMU_ERR_IRQ	MMU error.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
27:26	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
25	OVF_IRQ	Central Resource SBL overflow This event is triggered when one of the buffer in the central resource SBL overflows.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Bits	Field Name	Description	Type	Reset
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
23:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
21	CBUFF_IRQ	Circular buffer interrupt  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
20	PRV_DONE_IRQ	PREVIEW module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read too slowly from SDRAM. When this event is pending the module goes into transparent mode (output=input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
16	HIST_DONE_IRQ	HIST module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Bits	Field Name	Description	Type	Reset
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
8	CCDC_VD0_IRQ	CCDC module - programmable event 0. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
7:0	RESERVED	Reserved bit field. Write the reset value.	RW	0x0

### 1.6.2.6 ISP\_IRQ1STATUS

**Table 1-70. ISP\_IRQ1STATUS**

<b>Address Offset</b>	0x0000 0018	<b>Instance</b>	ISP
<b>Physical Address</b>	0x480B C018		
<b>Description</b>	INTERRUPT STATUS REGISTER TO DSP. IRQ1 STATUS LINE.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_VS_IRQ	SEC_ERR_IRQ	OCP_ERR_IRQ	MMU_ERR_IRQ	RESERVED		OVF_IRQ	RSZ_DONE_IRQ	RESERVED		CBUFF_IRQ	PRV_DONE_IRQ	CCDC_LSC_PREFETCH_ERROR	CCDC_LSC_PREFETCH_COMPLETED	CCDC_LSC_DONE	HIST_DONE_IRQ	RESERVED		H3A_AWB_DONE_IRQ	H3A_AF_DONE_IRQ	CCDC_ERR_IRQ	CCDC_VD2_IRQ	CCDC_VD1_IRQ	CCDC_VD0_IRQ	RESERVED							

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
30	SEC_ERR_IRQ	Security error READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
29	OCP_ERR_IRQ	ISP Interconnect error. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0

Bits	Field Name	Description	Type	Reset
28	MMU_ERR_IRQ	MMU error. If event is true, one needs to read the MMU_IRQSTATUS register to know the event source. Write in MMU_IRQSTATUS to clear the bit. READS: 0: event is false 1: event is true	R/W/1to Clr	0x0
27:26	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0
25	OVF_IRQ	Central Resource SBL overflow If event is true, one needs to check the SBL_PCR register to know the source. One needs to clear the SBL_PCR register first before clearing this bit. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	R/W/1to Clr	0x0
23:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0
21	CBUFF_IRQ	A circular buffer event is pending. Check submodule's interrupt status register. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
20	PRV_DONE_IRQ	PREVIEW module - processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read to slowly from SDRAM. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0

Bits	Field Name	Description	Type	Reset
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
16	HIST_DONE_IRQ	HIST module - processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow If event is true, one needs to clear the CCDC_FPC.FPERR bit first before clearing this bit. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
8	CCDC_VD0_IRQ	CCDC module - programmable event 0. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
7:0	RESERVED	Reserved bit field. Write the reset value.	R/W/1to Clr	0x0

### 1.6.2.7 TCTRL\_GRESET\_LENGTH

**Table 1-71. TCTRL\_GRESET\_LENGTH**

<b>Address Offset</b>	0x0000 0030																															
<b>Physical Address</b>	0x480B C030																<b>Instance</b> ISP															
<b>Description</b>	TIMING CONTROL - GLOBAL SHUTTER LENGTH REGISTER This register is used by the TIMING CTRL module to generate the cam_global_reset signal.																															
<b>Type</b>	RW																															
31 30 29 28 27 26 25 24								23 22 21 20 19 18 17 16								15 14 13 12 11 10 9 8								7 6 5 4 3 2 1 0								
RESERVED								LENGTH																								

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
23:0	LENGTH	Sets the length of the cam_global_reset signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. After signal assertion, the TCTRL_CTRL.GRESETEN bit is automatically cleared. The possible values are 0 to 2^24-1 cycles. The polarity of the cam_global_reset signal is set by the TCTRL_CTRL.GRESETPOL bit.	RW	0x000000

### 1.6.2.8 TCTRL\_PSTRB\_REPLAY

**Table 1-72. TCTRL\_PSTRB\_REPLAY**

Address Offset	0x0000 0034																														
Physical Address	0x480B C034															InstanceISP															
Description	TIMING CONTROL - PRESTROBE REPLAY REGISTER This register is used by the TIMING CTRL module to generate the prestrobe signal.																														
Type	RW																														

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNTER								DELAY																							

Bits	Field Name	Description	Type	Reset
31:25	COUNTER	Sets the number of PRESTROBE pulses after the original pulse. If this bit is set to 0, the PRESTROBE signal behavior is only controlled by TCTRL_FRAME.STRB, TCTRL_PSTRB_DELAY and TCTRL_PSTRB_LENGTH. If TCTRL_PSTRB_LENGTH=0, there is no replay. This bit is useful when one wants to enable red-eye removal.	RW	0x00
24:0	DELAY	Sets the delay for the PRESTROBE signal re-assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. The possible values are 0 to 2^25-1 cycles. If TCTRL_PSTRB_LENGTH=0, there is no replay. This bit field must not be set to 0 if the COUNTER is set to a value different of 0. This bit is useful when one wants to enable red-eye removal.	RW	0x0000000

### 1.6.2.9 ISP\_CTRL

**Table 1-73. ISP\_CTRL**

<b>Address Offset</b>		0x0000 0040																													
<b>Physical Address</b>		0x480B C040																													
<b>Description</b>		<b>Instance</b> ISP CONTROL REGISTER After reset, the parallel interface is selected and only the CCDC module data write port is enabled.																													
<b>Type</b>		RW																													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLUSH	JPEG_FLUSH	CCDC_WEN_POL	SBL_SHARED_RPORTB	RESERVED				SBL_AUTOIDLE	SBL_WR0_RAM_EN	SBL_WR1_RAM_EN	SBL_RD_RAM_EN	PREV_RAM_EN	CCDC_RAM_EN	SYNC_DETECT	RSZ_CLK_EN	PRV_CLK_EN	HIST_CLK_EN	H3A_CLK_EN	CBUFF_AUTOGATING	CCDC_CLK_EN	SHIFT	RESERVED	PAR_CLK_POL	PAR_BRIDGE	PAR_SER_CLK_SEL						

Bits	Field Name	Description	Type	Reset
31	FLUSH	CCDC memory flush Writing 1 in this bit flushes the CCDC memories in the central resource SBL. The SBL memories are always flushed by the end of frame. However, there are cases where the end of frame cannot be detected.	RW	0x0
30	JPEG_FLUSH	JPEG flush When a camera module outputs a JPEG bit stream, this bit must be set because the bit stream length may not be a multiple of 32 bits. Enabling this bit ensures that no data stay in the design internal FIFOs.	RW	0x0
29	CCDC_WEN_POL	Sets the polarity of the CCDC WEN bit. 0x0: Active low 0x1: Active high	RW	0x0
28	SBL_SHARED_RPORTB	Controls SBL shared read port B access 0x0: Read port used by preview module dark frame read 0x1: Read port used by CCDC module lens-shading compensation data read	RW	0x0
27:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
21	SBL_AUTOIDLE	Sets the SBL autoidle mode 0x0: Disabled 0x1: Enabled	RW	0x1
20	SBL_WR0_RAM_EN	This bit controls the SBL module WRITE0 RAM used by the RESIZER module. If the RESIZER module is disabled, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
19	SBL_WR1_RAM_EN	This bit controls the SBL module WRITE1 RAM. If the RESIZER module is the only module enabled to perform memory to memory resize operations, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
18	SBL_RD_RAM_EN	This bit controls the SBL module READ RAM. If no read requests are generated, this bit should be set to 0 to save power.  0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
17	PREV_RAM_EN	This bit controls the PREVIEW module RAM. If the PREVIEW module is not used, this bit should be set to 0 to save power.  0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
16	CCDC_RAM_EN	This bit controls the CCDC module RAM. If the CCDC module is not used, the bit should be set to 0 to save power.  0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
15:14	SYNC_DETECT	HS or VS synchronization signal detection It is sometimes necessary to detect the rising or falling edge of the horizontal and vertical synchro signals. When such event is detected, an interrupt is triggered if ISP_IRQ0ENABLE.HS_VS_IRQ = 1 or ISP_IRQ0ENABLE.HS_VS_IRQ = 1.  0x0: HS falling edge 0x1: HS rising edge 0x2: VS falling edge 0x3: VS rising edge	RW	0x0
13	RSZ_CLK_EN	RSZ module clock enable. This bit controls the clock distribution to the RSZ module.  0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible.  0x1: Enable clock. The module is fully functional.	RW	0x0
12	PRV_CLK_EN	PRV module clock enable. This bit controls the clock distribution to the PRV module.  0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible.  0x1: Enable clock. The module is fully functional.	RW	0x0
11	HIST_CLK_EN	HIST module clock enable. This bit controls the clock distribution to the HIST module.  0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible.  0x1: Enable clock. The module is fully functional.	RW	0x0
10	H3A_CLK_EN	H3A module clock enable. This bit controls the clock distribution to the H3A module.  0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible.  0x1: Enable clock. The module is fully functional.	RW	0x0
9	CBUFF_AUTOGATING	CBUFF module autogating feature control  0x0: CBUFF autogating feature is disabled. The CBUFF internal clock is free running.  0x1: CBUFF autogating feature is enabled. The CBUFF internal clock is only enabled when it is requested by the CBUFF module.	RW	0x1

Bits	Field Name	Description	Type	Reset
8	CCDC_CLK_EN	CCDC module clock enable. This bit controls the clock distribution to the CCDC module.  0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible.  0x1: Enable clock. The module is fully functional.	RW	0x0
7:6	SHIFT	Data lane shifter The parallel interface is a 12-bit interface. The CAMERA ISP has 14 data lanes but the full imaging pipeline only supports 10 bits. There are 2 main utilizations of the data lane shifter 1) Dynamic reduction: For example data from a 12 bit sensor can be converted into 10bit. 2) When a camera module as fewer than 12 data lanes, the ISP requires the pins to be connected on the least significant lanes. An issue occurs when a n-bit camera parallel interface can work in a m-bit mode with m<n. The ISP expects the m bits to be on the least significant data lanes whereas it is not correct. The data lane shifter takes place before the CCDC module  0x0: No shift. CAMEXT[13:0] -> CAM [13:0] 0x1: Shift by 2. CAMEXT[13:2] -> CAM [11:0] 0x2: Shift by 4 CAMEXT[13:4] -> CAM [9:0] 0x3: Shift by 6 CAMEXT[13:6] -> CAM [7:0]	RW	0x0
5	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
4	PAR_CLK_POL	This bit sets the pixel clock polarity on the parallel interface. The pixel clock is used for latching the pixel data into the CCDC module.  0x0: Clock not inverted. The data are sampled on the rising edge of the clock.  0x1: Clock inverted. The data are sampled on the falling edge of the clock.	RW	0x0
3:2	PAR_BRIDGE	This bit field controls the 8 to 16-bit bridge at the input of the CCDC module.  0x0: The bridge is disabled: no conversion. 0x1: Reserved 0x2: The bridge is enabled. The first byte is written to cam_d[7:0], the second byte is written to cam_d[15:8] 0x3: The bridge is enabled. The first byte is written to cam_d[15:8], the second byte is written to cam_d[7:0]	RW	0x0
1:0	PAR_SER_CLK_SEL	Selects the serial or parallel interface as the input to the preview hardware.  0x0: Selects the 12-bit parallel interface as the input to the CCDC module. 0x1: Reserved. 0x2: Reserved.	RW	0x0

#### 1.6.2.10 ISP\_SECURE

**Table 1-74. ISP\_SECURE**

<b>Address Offset</b>	0x0000 0044

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000000
0	SECURE	Secure mode: can only be set and reset by a secure request. If a non-secure transaction tries to modify this bit, the SEC_ERR_IRQ event is triggered.  0x0: Non -secure mode. 0x1: Secure mode.	RW	0x0

### 1.6.2.11 TCTRL\_CTRL

**Table 1-75. TCTRL\_CTRL**

Address Offset		0x0000 0050																																	
Physical Address		0x480B C050																Instance																ISP	
Description		TIMING CONTROL - CONTROL REGISTER																																	
Type		RW																																	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GRESETDIR	GRESETPOL	GRESETEN	INSEL		STRBPSTRBPOL	RESERVED	SHUTPOL	STRBEN	PSTRBEN	SHUTEN	RESERVED	DIVC					DIVB					DIVA									

Bits	Field Name	Description	Type	Reset
31	GRESETDIR	Sets the direction of the cam_global_reset signal. 0x0: INPUT. cam_global_reset is an input to the TIMING CONTROL module. cam_global_reset is externally generated. 0x1: OUTPUT. cam_global_reset is an output of the TIMING CONTROL module. cam_global_reset is internally generated. If GRESETEN is set to 1, the internally generated cam_global_reset triggers the generation of the PRESTROBE, STROBE and SHUTTER signals. The frame counters are ignored.	RW	0x0
30	GRESETPOL	Sets the polarity of the global reset signal: cam_global_reset. It applies whatever the direction of the cam_global_reset signal: input or output. 0x0: active high 0x1: active low	RW	0x0

Bits	Field Name	Description	Type	Reset
29	GRESETEN	Triggers the generation of the cam_global_reset signal. The signal is asserted immediately. If enabled, the cam_global_reset signal is asserted for TCTRL_GRESET_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. The polarity of the cam_global_reset signal is set with TCTRL_CTRL.GRESETPOL. Enabling this bit triggers the generation of the cam_shutter and cam_strobe signals (if previously enabled). The frame counters must be set to 0 when this bit is set to 1 and GRESETDIR is set a OUTPUT.	RW	0x0
28:27	INSEL	Sets the mode that triggers the SHUTTER, PRESTROBE and STROBE signals.  0x0: Video Port. The VS sync pulse at the input of the CCDC module is used to count the frames. The source of the VS pulse is selected by the ISP_CTRL [1:0] PAR_SER_CLK_SEL register.  0x1: Reserved.  0x2: Reserved.  0x3: GRESET. The cam_global_reset input signal triggers the SHUTTER, PRESTROBE and STROBE signals. In this mode, there are no frame counters. The delay counters start decrementing as soon as the cam_global_reset signal is asserted. The polarity of the cam_global_reset signal is set with TCTRL_CTRL.GRESETPOL.	RW	0x0
26	STRBPSTRBPOL	Sets the polarity of the strobe and prestrobe signals.  0x0: Active high 0x1: Active low	RW	0x0
25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
24	SHUTPOL	Sets the polarity of the mechanical shutter signal: cam_shutter  0x0: Active high 0x1: Active low	RW	0x0
23	STRBEN	Flash strobe signal enable. If enabled, the STROBE signal is asserted after TCTRL_FRAME.STRB frames have been received and a delay of TCTRL_STRB_DELAY cycles have passed. The STROBE signal is asserted for TCTRL_STRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0
22	PSTRBEN	Flash prestrobe signal enable. If enabled, the PRESTROBE signal is asserted after TCTRL_FRAME.PSTRB frames have been received and a delay of TCTRL_PSTRB_DELAY cycles have passed. The PRESTROBE signal is asserted for TCTRL_PSTRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0
21	SHUTEN	Mechanical shutter signal enable. If enabled, the SHUTTER signal is asserted after TCTRL_FRAME.SHUT frames have been received and a delay of TCTRL_SHUT_DELAY cycles have passed. The SHUTTER signal is asserted for TCTRL_SHUT_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0
20:19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
18:10	DIVC	Sets the clock divisor value for the CNTCLK clock generation based on the CAM_MCLK input clock. CNTCLK is an internal clock used by the TIMING CTRL module counters. Usually, CNTCLK = CAM_MCLK/DIVC, except for some particular values shown hereafter.  0x0: No clock. CNTCLK is gated.	RW	0x000
9:5	DIVB	Sets the clock divisor value for the cam_xclkb clock generation based on the CAM_MCLK input clock. Usually, cam_xclkb = CAM_MCLK/DIVB, except for some particular values shown hereafter. This bit field is not reset by a soft reset; a hard reset is required. It enables to keep the clock configuration stable through a soft reset.  0x0: cam_xclkb = stable low level. Divider disabled. 0x1: cam_xclkb = stable high level. Divider disabled. 0x1F: cam_xclkb = cam_xclk. Bypass.	RW	0x00
4:0	DIVA	Sets the clock divisor value for the cam_xclka clock generation based on the CAM_MCLK input clock. Usually, cam_xclka = CAM_MCLK/DIVA, except for some particular values shown hereafter. This bit field is not reset by a soft reset; a hard reset is required. It enables to keep the clock configuration stable through a soft reset.  0x0: cam_xclka = stable low level. Divider disabled. 0x1: cam_xclka = stable high level. Divider disabled. 0x1F: cam_xclka = cam_xclk. Bypass.	RW	0x00

### 1.6.2.12 TCTRL\_FRAME

**Table 1-76. TCTRL\_FRAME**

<b>Address Offset</b>	0x0000 0054																																																														
<b>Physical Address</b>	0x480B C054								<b>Instance</b>	ISP																																																					
<b>Description</b>	TIMING CONTROL - FRAME REGISTER This register is used by the TIMING CTRL module to generate the SHUTTER, PRESTROBE and STROBE signals.																																																														
<b>Type</b>	RW																																																														
31		30		29		28		27		26		25		24		23		22		21		20		19		18		17		16		15		14		13		12		11		10		9		8		7		6		5		4		3		2		1		0	
RESERVED																STRB						PSTRB						SHUT																																			
<b>Bits</b>		<b>Field Name</b>				<b>Description</b>										<b>Type</b>				<b>Reset</b>																																											
31:18		RESERVED				Write 0s for future compatibility. Reads returns 0.										RW				0x0000																																											
17:12		STRB				Frame counter for the STROBE signal generation. From 0 to 63 frames. This bit field is ignored if TCTRL.INSEL=GRESET.										RW				0x00																																											
11:6		PSTRB				Frame counter for the PRESTROBE signal generation. From 0 to 63 frames. This bit field is ignored if TCTRL.INSEL=GRESET.										RW				0x00																																											
5:0		SHUT				Frame counter for the SHUTTER signal generation. From 0 to 63 frames. This bit field is ignored if TCTRL.INSEL=GRESET.										RW				0x00																																											

### 1.6.2.13 TCTRL\_PSTRB\_DELAY

**Table 1-77. TCTRL\_PSTRB\_DELAY**

<b>Address Offset</b>	0x0000 0058																																
<b>Physical Address</b>	0x480B C058																<b>Instance</b>	ISP															
<b>Description</b>	TIMING CONTROL - PRE STROBE DELAY REGISTER This register is used by the TIMING CTRL module to generate the PRESTROBE signal.																																
<b>Type</b>	RW																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED								DELAY																									
<b>Bits</b>	<b>Field Name</b>							<b>Description</b>																<b>Type</b>				<b>Reset</b>					
31:25	RESERVED							Write 0s for future compatibility. Reads returns 0.																RW				0x00					
24:0	DELAY							Sets the delay for the PRESTROBE signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. The possible values are 0 to 2^25-1 cycles.																RW				0x0000000					

#### 1.6.2.14 TCTRL\_STRB\_DELAY

**Table 1-78. TCTRL\_STRB\_DELAY**

<b>Address Offset</b>	0x0000 005C																																
<b>Physical Address</b>	0x480B C05C																<b>Instance</b>	ISP															
<b>Description</b>	TIMING CONTROL - STROBE DELAY REGISTER This register is used by the TIMING CTRL module to generate the STROBE signal.																																
<b>Type</b>	RW																																
31 30 29 28 27 26 25 24								23 22 21 20 19 18 17 16								15 14 13 12 11 10 9 8								7 6 5 4 3 2 1 0									
RESERVED								DELAY																									
<b>Bits</b>	<b>Field Name</b>							<b>Description</b>																								<b>Type</b>	<b>Reset</b>
31:25	RESERVED							Write 0s for future compatibility. Reads returns 0.																								RW	0x00
24:0	DELAY							Sets the delay for the cam_strobe signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. The possible values are 0 to 2^25-1 cycles.																								RW	0x0000000

#### 1.6.2.15 TCTRL\_SHUT\_DELAY

**Table 1-79. TCTRL\_SHUT\_DELAY**

<b>Address Offset</b>	0x0000 0060																																
<b>Physical Address</b>	0x480B C060																<b>Instance</b>	ISP															
<b>Description</b>	TIMING CONTROL - SHUTTER DELAY REGISTER This register is used by the TIMING CTRL module to generate the SHUTTER signal.																																
<b>Type</b>	RW																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED								DELAY																									

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
24:0	DELAY	Sets the delay for the cam_shutter signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. The possible values are 0 to 2 <sup>25</sup> -1 cycles.	RW	0x0000000

### 1.6.2.16 TCTRL\_PSTRB\_LENGTH

**Table 1-80. TCTRL\_PSTRB\_LENGTH**

<b>Address Offset</b>	0x0000 0064																																
<b>Physical Address</b>	0x480B C064																<b>Instance</b>	ISP															
<b>Description</b>	TIMING CONTROL - PRESTROBE LENGTH REGISTER This register is used by the TIMING CTRL module to generate the PRESTROBE signal.																																
<b>Type</b>	RW																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED								LENGTH																									
<b>Bits</b>		<b>Field Name</b>						<b>Description</b>																<b>Type</b>		<b>Reset</b>							
31:24		RESERVED						Write 0s for future compatibility. Reads returns 0.																RW		0x00							
23:0		LENGTH						Sets the length of the PRESTROBE signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. After signal assertion, the TCTRL_CTRL.PSTRBEN bit is automatically cleared. The possible values are 0 to 2^24-1 cycles.																RW		0x000000							

### 1.6.2.17 TCTRL\_STRB\_LENGTH

**Table 1-81. TCTRL\_STRB\_LENGTH**

<b>Address Offset</b>	0x0000 0068																																
<b>Physical Address</b>	0x480B C068																<b>Instance</b>	ISP															
<b>Description</b>	TIMING CONTROL - STROBE LENGTH REGISTER This register is used by the TIMING CTRL module to generate the STROBE signal.																																
<b>Type</b>	RW																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED								LENGTH																									
<b>Bits</b>		<b>Field Name</b>						<b>Description</b>																<b>Type</b>		<b>Reset</b>							
31:24		RESERVED						Write 0s for future compatibility. Reads returns 0.																RW		0x00							
23:0		LENGTH						Sets the length of the cam_strobe signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. After signal assertion, the TCTRL_CTRL.STRBEN bit is automatically cleared. The possible values are 0 to 2^24-1 cycles.																RW		0x000000							

### 1.6.2.18 TCTRL\_SHUT\_LENGTH

**Table 1-82. TCTRL\_SHUT\_LENGTH**

<b>Address Offset</b>	0x0000 006C																																																																																												
<b>Physical Address</b>	0x480B C06C															<b>Instance</b>	ISP																																																																												
<b>Description</b>	TIMING CONTROL - SHUTTER LENGTH REGISTER This register is used by the TIMING CTRL module to generate the SHUTTER signal.																																																																																												
<b>Type</b>	RW

2	IRQ_CBUFF0_OVR	Buffer overflow event. Check the functional specification for more details.  0x0: interrupt is masked  0x1: Interrupt is enabled	RW	0x0
1	IRQ_CBUFF0_INVALID	Invalid access. Check the functional specification for more details.  0x0: interrupt is masked  0x1: Interrupt is enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
0	IRQ_CBUFF0_READY	The CPUW0 physical buffer is ready to be accessed by the CPU. Check the functional specification for more details.  0x0: interrupt is masked 0x1: Interrupt is enabled	RW	0x0

### 1.6.3.5 CBUFFx\_CTRL

**Table 1-87. CBUFFx\_CTRL**

<b>Address Offset</b>	0x0000 0020 + (0x4 * x)	<b>Index</b>	x = 0 to 1
<b>Physical Address</b>	0x480B C120 + (0x4 * x)	<b>Instance</b>	ISP_CBUFF
<b>Description</b>	Circular buffer x control register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WCOUNT		BCF				ALLOW_NW_EQ_CPUW		DONE	RWMODE	ENABLE					

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000000
9:8	WCOUNT	Window count  0x0: 2 windows  0x1: 4 windows  0x2: 8 windows  0x3: 16 windows	RW	0x0
7:4	BCF	This register controls the bandwidth control feedback loop output. Functionality depends on subsystem integration. 0: Control loop disabled. Data read from memory is free running. 1-15: The control feedback loop signal is asserted when the window count available for ISP is below (<) the threshold. In other words at least (>=) BCF windows are available for ISP access when this signal is released.	RW	0x0

Bits	Field Name	Description	Type	Reset
3	ALLOW_NW_EQ_CPUW	<p>Allow NW=CPUW. Better buffer utilization when ISP does not use the next write window.</p> <p>0x0: When the CPUW and the NW pointers designate the same window and accesses are effectively performed to those windows an overflow event occurs. This happens when</p> <ul style="list-style-type: none"> <li>- the CPU has received an READY IRQ for that window indicating that it can be accessed and</li> <li>- the ISP performs an access to that window. ISP accesses are tracked based on OCPI activity.</li> </ul> <p>0x1: When the CPUW and the CW pointers designate the same window and accesses are effectively performed to those windows an overflow event occurs. This happens when</p> <ul style="list-style-type: none"> <li>- the CPU has received an READY IRQ for that window indicating that it can be accessed and</li> <li>- the ISP performs an access to that window. ISP accesses are tracked based on OCPI activity.</li> </ul>	RW	0x0
2	DONE	<p>Write this bit to 1 to indicate the CPU has finished processing its physical buffer. This bit is automatically cleared by hardware, reads always return 0.</p> <p>0x0: No effect.</p> <p>0x1: The CPU has completely processed the CPUW physical buffer.</p>	W	0x0
1	RWMODE	<p>Selects read or write mode</p> <p>0x0: Write mode. HW writes and CPU reads the physical space. CPU accesses are out of CBUFF module's scope, therefore only writes are permitted between CBUFF0_START and CBUFF0_END.</p> <p>0x1: Read mode. HW reads and CPU writes the physical space. CPU accesses are out of CBUFF module's scope, therefore only reads are permitted between CBUFF0_START and CBUFF0_END.</p>	RW	0x0
0	ENABLE	<p>Enable/disable</p> <p>0x0: Disables the circular buffer 0; this resets the internal state of circular buffer 0. All accesses received on OCPI are transmitted to OCPO without modification. Disabling the module takes effect immediately. It is SW responsibility to ensure that no more accesses to CBUFF0 are outstanding before disabling the module. Otherwise memory corruption may occur.</p> <p>0x1: Enable the circular buffer 0. All accesses between CBUFF0_START and CBUFF0_END are processed by the module.</p>	RW	0x0

### 1.6.3.6 CBUFFx\_STATUS

**Table 1-88. CBUFFx\_STATUS**

<b>Address Offset</b>	0x0000 0030 + (0x4 * x)	<b>Index</b>	x = 0 to 1
<b>Physical Address</b>	0x480B C130 + (0x4 * x)	<b>Instance</b>	ISP_CBUFF
<b>Description</b>	Threshold value used to check if the CW or NW windows are full.		
<b>Type</b>	R

[www.ti.com](http://www.ti.com)

<b>Bits</b>	<b>Field Name</b>	<b>Description</b>	<b>Type</b>	<b>Reset</b>
31:24	RESERVED	Reads returns 0.	R	0x00
23:20	RESERVED	Reads returns 0.	R	0x0
19:16	NW	Next window number. Valid values depend on the CBUFF_CTRL.WCOUNT register.	R	0x1
15:12	RESERVED	Reads returns 0.	R	0x0
11:8	CW	Current window number. Valid values depend on the CBUFF_CTRL.WCOUNT register.	R	0x0
7:4	RESERVED	Reads returns 0.	R	0x0
3:0	CPUW	Current CPU window number. Valid values depend on the CBUFF_CTRL.WCOUNT register.	R	0x0

### 1.6.3.7 CBUFFx\_START

**Table 1-89. CBUFFx\_START**

<b>Address Offset</b>	0x0000 0040 + (0x4 * x)	<b>Index</b>	x = 0 to 1
<b>Physical Address</b>	0x480B C140 + (0x4 * x)	<b>Instance</b>	ISP_CBUFF
<b>Description</b>	Start address of the virtual space managed by circular buffer x. Start address of the 1st physical buffer managed by circular buffer x.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR																RESERVED															

Bits	Field Name	Description	Type	Reset
31:3	ADDR	Address, in 64 bit words.	RW	0x00000000
2:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

### 1.6.3.8 CBUFFx\_END

**Table 1-90. CBUFFx\_END**

<b>Address Offset</b>	0x0000 0050 + (0x4 * x)	<b>Index</b>	x = 0 to 1
<b>Physical Address</b>	0x480B C150 + (0x4 * x)	<b>Instance</b>	ISP_CBUFF
<b>Description</b>	End address of the virtual space managed by circular buffer x.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR																RESERVED															

Bits	Field Name	Description	Type	Reset
31:3	ADDR	Address, in 64 bit words.	RW	0x00000000
2:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

### 1.6.3.9 CBUFFx\_WINDOWSIZE

**Table 1-91. CBUFFx\_WINDOWSIZE**

<b>Address Offset</b>	0x0000 0060 + (0x4 * x)	<b>Index</b>	x = 0 to 1
<b>Physical Address</b>	0x480B C160 + (0x4 * x)	<b>Instance</b>	ISP_CBUFF
<b>Description</b>	Defines the window size.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								SIZE																						RESERVED	

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
23:3	SIZE	Size, in 64 bit words.	RW	0x000000
2:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

### 1.6.3.10 CBUFFx\_THRESHOLD

**Table 1-92. CBUFFx\_THRESHOLD**

<b>Address Offset</b>	0x0000 0070 + (0x4 * x)	<b>Index</b>	x = 0 to 1
<b>Physical Address</b>	0x480B C170 + (0x4 * x)	<b>Instance</b>	ISP_CBUFF
<b>Description</b>	Threshold value used to check if a write window is full.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								THRESHOLD																							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
23:0	THRESHOLD	Threshold value, in bytes.	RW	0x000000

## 1.6.4 ISP\_CCDC Register Descriptions

### 1.6.4.1 CCDC\_PID

**Table 1-93. CCDC\_PID**

Address Offset	0x0000 0000		
Physical Address	0x480B C600	Instance	ISP_CCDC
Description	PERIPHERAL ID REGISTER		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								TID				CID				RESERVED															

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x00
23:16	TID	Peripheral identification: CCDC module	R	0x01
15:8	CID	Class identification: Camera ISP	R	0xFE
7:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x00

### 1.6.4.2 CCDC\_PCR

**Table 1-94. CCDC\_PCR**

Address Offset		0x0000 0004																Instance ISP_CCDC															
Physical Address		0x480B C604																															
Description		PERIPHERAL CONTROL REGISTER																															
Type		RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED																												RESERVED	RESERVED	BUSY	ENABLE		
Bits		Field Name		Description																Type		Reset											
31:4		RESERVED		Write 0s for future compatibility. Reads returns 0.																RW		0x0000000											
3		RESERVED		Reserved bit field. Write the reset value.																RW		0x0											
2		RESERVED		Reserved bit field. Write the reset value.																RW		0x0											
1		BUSY		CCDC module busy. 0x0: Module is not busy. 0x1: Module is busy.																R		0x0											
0		ENABLE		CCDC module enable. This bit is latched by VD (start of frame) 0x0: Disable module. 0x1: Enable module.																RW		0x0											

### 1.6.4.3 CCDC\_SYN\_MODE

**Table 1-95. CCDC\_SYN\_MODE**

Address Offset	0x0000 0008																																															
Physical Address	0x480B C608																Instance																ISP_CCDC															
Description	SYNC and mode set register																																															
Type	RW																																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																	
RESERVED												SDR2RSZ	VP2SDR	WEN	VDHDE	FLDSTAT	LPF	INPMOD	PACK8	DATSIZ				FLDMODE	DATAPOL	EXWEN	FLDPOL	HDPOL	VPOL	FLDOUT	VDHOUT																	

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
19	SDR2RSZ	Memory port output into the RESIZER input. Controls whether or not the memory port output data are forwarded to the RESIZER module input port. This does not depend on the state of the CCDC_SYN_MODE.WEN bit. This bit must only be set if the CCDC module receives directly YUV422 data. The input frame size to the RESIZER module is the same as the output frame size to the memory port. The data are simultaneously written to memory if the WEN bit is set while sending the same data to the RESIZER module. The PREVIEW module can also write to the RESIZER module: this bit takes precedence over the PREVIEW module settings. This bit is latched by the VS sync pulse.  0x0: Disable 0x1: Enable	RW	0x0
18	VP2SDR	Video port output enable to the output formatter.. Controls whether the video port data is forwarded to the output formatter or not. If CCDC_SYN_MODE.WEN= 1, the video port data is written to memory. Note that if field is set, then SDRAM line (VERT_START.SLVx) and pixel start (HORZ_INFO.SPH) are with respect to the video port output (and not the original input) This bit field is latched by the VS sync pulse.  0x0: Disable 0x1: Enable	RW	0x0
17	WEN	Data write enable. Controls whether the CCDC module output data are written to memory or not. This bit field is latched by the VS sync pulse.  0x0: Disable 0x1: Enable	RW	0x0
16	VDHDEN	Timing generator enable. If HS/VS sync pulses are defined as output signals, activates the internal timing generator. If HS/VS sync pulses are defined as input signals, activates internal timing generator to synchronize with HS/VS. This bit must be set to 1 when HS and VS signals are used.  0x0: Disable 0x1: Enable	RW	0x0
15	FLDSTAT	cam_fld signal status. This bit field applies only if the CCDC module is configured to work in interlaced mode: CCDC_SYN_MODE.FLDMODE = "interlaced". It indicates the status of the current field.  0x0: Odd field 0x1: Even field	R	0x0
14	LPF	Three-tap low pass (antialiasing) filter enable. This bit field is latched by the VS sync pulse.  0x0: Filter is disabled. 0x1: Filter is enabled.	RW	0x0

Bits	Field Name	Description	Type	Reset
13:12	INPMOD	cam_d format in SYNC mode. Sets the data input format.  0x0: Raw data  0x1: YCbCr data on 16 bits. It is required to enable the 8 to 16-bit bridge in the ISP_CTRL register.  0x2: YCbCr data on 8 bits.	RW	0x0
11	PACK8	Data packing. Sets the data packing configuration when the data is written to memory.  0x0: Normal mode: 16 bits/pixel.  0x1: Pack mode: 8 bits/pixel.	RW	0x0
10:8	DATSIZ	cam_d signal width in SYNC mode. Valid only when CCDC_SYN_MODE.INPMOD = "raw data".  0x0: cam_d is 8 bits but the 8 to 16-bit bridge is enabled in the ISP_CTRL register.  0x4: cam_d is 12 bits 0x5: cam_d is 11 bits 0x6: cam_d is 10 bits 0x7: cam_d is 8 bits	RW	0x0
7	FLDMODE	cam_fld signal mode.  0x0: Progressive mode. cam_fld not used.  0x1: Interlaced mode. cam_fld used.	RW	0x0
6	DATAPOL	cam_d signal polarity.  0x0: Normal  0x1: One's complement	RW	0x0
5	EXWEN	External write enable selection. The cam_wen signal can be used as an external memory write-enable signal. The data is stored to memory only if cam_hs, cam_vs and cam_wen signals are asserted.  0x0: cam_wen is not used.  0x1: cam_wen is used	RW	0x0
4	FLDPOL	cam_fld signal polarity.  0x0: Positive  0x1: Negative	RW	0x0
3	HDPOL	Sets the cam_hs signal polarity.  0x0: Positive  0x1: Negative	RW	0x0
2	VDPOL	cam_vs signal polarity  0x0: Positive  0x1: Negative	RW	0x0
1	FLDOUT	cam_fld signal direction.  0x0: Input  0x1: Output	RW	0x0
0	VDHDOUT	cam_hs and cam_vs signal directions.  0x0: Input  0x1: Output	RW	0x0

### 1.6.4.4 CCDC\_HD\_VD\_WID

**Table 1-96. CCDC\_HD\_VD\_WID**

<b>Address Offset</b>	0x0000 000C	<b>Instance</b>	ISP_CCDC
<b>Physical Address</b>	0x480B C60C		
<b>Description</b>	SYNC WIDTH CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								HDW								RESERVED								VDW							

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
27:16	HDW	Sets the width of the HS sync pulse if set as output. The width of the pulse is (HDW+1) pixel clocks. Not used when HS/VS sync pulses are input signals (CCDC_SYN_MODE.VDHDOUT = 0). This bit field is latched by the VS sync pulse.	RW	0x000
15:12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
11:0	VDW	Sets the width of the VS sync pulse is set as output. The width of the pulse is (VDW+1) lines. Not used when HS/VS sync pulses are input signals (CCDC_SYN_MODE.VDHDOUT = 0). This bit field is latched by the VS sync pulse.	RW	0x000

### 1.6.4.5 CCDC\_PIX\_LINES

**Table 1-97. CCDC\_PIX\_LINES**

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	ISP_CCDC
<b>Physical Address</b>	0x480B C610		
<b>Description</b>	SIZE CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPLN																HLPFRF															

Bits	Field Name	Description	Type	Reset
31:16	PPLN	Pixels per line Sets the number of pixel clock periods in one line. HD period = (PPLN + 1) pixel clocks. Not used when HS/VS sync pulses are input signals (CCDC_SYN_MODE.VDHDOUT = 0). This bit fields is latched by the VS sync pulse	RW	0x0000
15:0	HLPFRF	Half line per field or frame Sets the number of half lines per frame or field. VD period = (HLPFRF + 1)/2 lines. Not used when HS/VS sync pulses are input signals (CCDC_SYN_MODE.VDHDOUT = 0). Sets the internal timing generator to generate the correct number of HS pulses in between two VS pulses. If the sensor is interlaced, with a total of N lines, then this field must be set to N. This means that N half lines are written for each field. If the sensor is progressive, then this register must be set to be twice the number of lines to be written. For example, if sensor outputs N lines, this field must be set to 2N. This bit fields is latched by the VS sync pulse.	RW	0x0000

### 1.6.4.6 CCDC\_HORZ\_INFO

**Table 1-98. CCDC\_HORZ\_INFO**

Address Offset		0x0000 0014																		Instance		ISP_CCDC															
Physical Address		0x480B C614																																			
Description		HORIZONTAL PIXEL INFO REGISTER																																			
Type		RW																																			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED	SPH																RESERVED	NPH															

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
30:16	SPH	Start pixel horizontal Sets the pixel clock position at which data output to memory begins. It is measured from the start of HS. This bit fields is latched by the VS sync pulse.	RW	0x0000
15	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
14:0	NPH	Number of pixels horizontal Sets the number of horizontal pixels output to memory. The number of pixels output is (NPH + 1). This bit fields is latched by the VS sync pulse.	RW	0x0100

### 1.6.4.7 CCDC\_VERT\_START

**Table 1-99. CCDC\_VERT\_START**

Address Offset		0x0000 0018																Instance		ISP_CCDC															
Physical Address		0x480B C618																																	
Description		VERTICAL LINE START REGISTER																																	
Type		RW																																	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED	SLV0																RESERVED	SLV1															

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
30:16	SLV0	Start line vertical - field0 Sets the line at which data output to memory begins. It is measured from the start of the VS sync pulse. This bit field is latched by the VS sync pulse.	RW	0x0000
15	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
14:0	SLV1	Start line vertical - field1 Sets the line at which data output to memory begins. It is measured from the start of the VS sync pulse. For a progressive sensor, this bit field is ignored. This bit field is latched by the VS sync pulse.	RW	0x0000

### 1.6.4.8 CCDC\_VERT\_LINES

**Table 1-100. CCDC\_VERT\_LINES**

<b>Address Offset</b>	0x0000 001C	<b>Instance</b>	ISP_CCDC
<b>Physical Address</b>	0x480B C61C		
<b>Description</b>	VERTICAL LINE NUMBER REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																NLV															

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
14:0	NLV	Number of lines - vertical direction Sets the number of vertical lines output to memory. The number of lines output is (NLV + 1). This bit is latched by the VS sync pulse.	RW	0x0000

### 1.6.4.9 CCDC\_CULLING

**Table 1-101. CCDC\_CULLING**

<b>Address Offset</b>	0x0000 0020	<b>Instance</b>	ISP_CCDC
<b>Physical Address</b>	0x480B C620		
<b>Description</b>	CULL CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CULHEVN								CULHODD								RESERVED								CULV							

Bits	Field Name	Description	Type	Reset
31:24	CULHEVN	Horizontal culling patterns for even lines. Sets an 8-bit mask (0:cull, 1:retain). The LSB is the 1st pixel and the MSB is the 8th pixel. Then, the pattern repeats. This bit field is latched by the VS sync pulse.	RW	0xFF
23:16	CULHODD	Horizontal culling patterns for odd lines. Sets an 8-bit mask (0:cull, 1:retain). The LSB is the 1st pixel and the MSB is the 8th pixel. Then, the pattern repeats. This bit field is latched by the VS sync pulse.	RW	0xFF
15:8	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
7:0	CULV	Vertical culling pattern. Sets an 8-bit mask (0:cull, 1:retain). The LSB is the 1st line and the MSB is the 8th line. Then, the pattern repeats. This bit field is latched by the VS sync pulse.	RW	0xFF

### 1.6.4.10 CCDC\_HSIZE\_OFF

**Table 1-102. CCDC\_HSIZE\_OFF**

<b>Address Offset</b>	0x0000 0024																														
<b>Physical Address</b>	0x480B C624															<b>Instance</b>	ISP_CCDC														
<b>Description</b>	HORIZONTAL SIZE REGISTER																														
<b>Type</b>	RW																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																LNOFST															
<b>Bits</b>	<b>Field Name</b>		<b>Description</b>															<b>Type</b>	<b>Reset</b>												
31:16	RESERVED		Write 0s for future compatibility. Reads returns 0.															RW	0x0000												
15:0	LNOFST		Line offset. Sets the offset for each output line to memory. The offset must be a multiple of 32 bytes: the 5 least significant bits are ignored. Usually the line offset is equal to the line length in bytes, that is, the line length must be a multiple of 32 bytes. If LNOFST = 0, the data is written again and again over the same line. For optimal performance in the system, the address offset must be on a 256-byte boundary. This bit field is latched by the VS sync pulse.															RW	0x0000												

#### 1.6.4.11 CCDC\_SDOFST

**Table 1-103. CCDC\_SDOFST**

Address Offset		0x0000 0028																													
Physical Address		0x480B C628																													
Description		MEMORY OFFSET REGISTER

RESERVED																								FPERR				FPCEN				FPNUM																																																																																																																																																																																																																															
Bits		Field Name																Description																Type		Reset																																																																																																																																																																																																																											
31:17		RESERVED																Write 0s for future compatibility. Reads returns 0.																RW		0x0000																																																																																																																																																																																																																											
16		FPERR																Fault pixel correction error This bit is set when the CCDC module is unable to fetch the required fault pixel table entry in time. Write 1 to clear the error or end_of_frame clears it automatically for the next frame. For example, the current pixel being processed has coordinates of 256/512 (256th line and 512th pixel in that line) and it must be corrected. If the entry in the fault pixel table that must be used has coordinates 256/256, then the current pixel cannot be corrected since the correct entry is not loaded in time. Note that there is no error recovery mechanism in the CCDC; if this bit is set at anytime in a frame, there are no more fault pixels corrected in that frame. Firmware is responsible for making sure that there is enough bandwidth in the system to allow for loading of the fault pixel table. Alternately, decreasing the frequency of the fault pixels to be corrected enhances the chances of this bit not being set.  0x0: No error 0x1: Error																RW		0x0																																																																																																																																																																																																																											
15		FPCEN																Fault pixel correction enable. Upon setting this bit, and as long as it remains enabled, the fault pixel logic continues to request data and just start over for next frame once the last data of current frame has been received. As soon as the register is set the data are fetched. To disable fault pixel correction, users can write a 0 at any time. However, the disabling only applies after the current frame is processed (busy bit for current frame is 0) This bit should only be written after the FPC_ADDR register below has been set. Also, the other fields in this register have to be set prior to enabling this bit. The required process is: Write(FPC_ADDR) Write(FPC) with this bit (FPC.FPCEN) turned off Write(FPC) with this bit (FPC.FPCEN) turned on while other fields are same as previous write  0x0: Disable 0x1: Enable																RW		0x0																																																																																																																																																																																																																											
14:0		FPNUM																Number of fault pixels to be corrected in the frame This field should not be changed when the FPCEN is enabled at any time																RW		0x0000

#### 1.6.4.31 CCDC\_VP\_OUT

**Table 1-123. CCDC\_VP\_OUT**

Address Offset		0x0000 0094																																															
Physical Address		0x480B C694																Instance																ISP_CCDC															
Description		VIDEO PORT OUTPUT REGISTER																																															
Type		RW																																															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	VERT_NUM															HORZ_NUM										HORZ_ST					

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
30:17	VERT_NUM	Number of vertical lines to clock out the video. If the data reformatter is turned off, then the number of lines that can be clocked out of the video port must be at least 1 line less than the number of lines input from the sensor. If the data reformatter is turned on, then the number of lines that can be clocked out of the video port must be less than (CCDC_FMT_VERT.FMTLNV - 1) * (CCDC_FMTCFG.LNUM + 1) The video port output VS pulse is generated right from the first video port input VS itself.	RW	0x0000
16:4	HORZ_NUM	Number of horizontal pixel to clock out the video port. The minimum value allowed is 2 pixels. The maximum offset allowed is 1376 if original input is broken down to 4 lines. The maximum offset allowed is 1376 if original input is broken down to 3 lines. The maximum offset allowed is 2*1376 if original input is broken down to 2 lines. The maximum offset allowed is 4*1376 if original input is broken down to 1 line.	RW	0x0000
3:0	HORZ_ST	Horizontal start pixel in each output line. The maximum value allowed is 15. The video port output HSYNC pulse is generated from this position on for each line. To be able to select an offset higher than 15, the input settings to the data reformatter must be configured appropriately. The purpose of this parameter is to allow for sensors that can read out a parallelogram image rather than a rectangular image.	RW	0x0

#### 1.6.4.32 CCDC\_LSC\_CONFIG

**Table 1-124. CCDC\_LSC\_CONFIG**

Address Offset	0x0000 0098		
Physical Address	0x480B C698	Instance	ISP_CCDC
Description	LENS SHADING COMPENSATION CONTROL AND STATUS REGISTER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GAIN_MODE_M		RESERVED		GAIN_MODE_N		BUSY		AFTER_REFORMATTER		RESERVED		GAIN_FORMAT		ENABLE	

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0s for future compatibility. Reads return zero.	RW	0x00000
14:12	GAIN_MODE_M	Define the horizontal dimension of a paxel. Possible values are listed below 0x2: Paxel is 4 pixels tall (M=4) 0x3: Paxel is 8 pixels tall (M=8) 0x4: Paxel is 16 pixels tall (M=16) 0x5: Paxel is 32 pixels tall (M=32) 0x6: Paxel is 64 pixels tall (M=64)	RW	0x6
11	RESERVED	Write 0s for future compatibility. Reads return zero.	R	0x0
10:8	GAIN_MODE_N	Define the vertical dimension of a paxel. Possible values are listed below 0x2: Paxel is 4 pixels tall (N=4) 0x3: Paxel is 8 pixels tall (N=8) 0x4: Paxel is 16 pixels tall (N=16) 0x5: Paxel is 32 pixels tall (N=32) 0x6: Paxel is 64 pixels tall (N=64)	RW	0x6
7	BUSY	Module busy or idle 0x0: The module is idle 0x1: The module is busy	R	0x0
6	AFTER_REFORMATTER	Chooses if lens-shading compensation is done before or after data reformatting 0x0: Lens-shading is done before data reformatting. H3A, HIST and PREVIEW receives shading compensated data 0x1: Data received by H3A isn't compensated. Data received by PREVIEW and HIST is compensated.	RW	0x0
5:4	RESERVED	Write 0s for future compatibility. Reads return zero.	RW	0x0
3:1	GAIN_FORMAT	Sets gain table format 0x0: Coded as 8-bit fraction Range from 0 to 255/256 0x1: Coded as 8-bit fraction + 1.0 of base. Range from 1 to 1+255/256 0x2: Coded as 1-bit integer, 7-bit fraction. Range from 0 to 1+127/128 0x3: Coded as 1-bit integer, 7-bit fraction + 1.0 Range from 1 to 2+127/128 0x4: Coded as 2-bit integer, 6-bit fraction Range from 0 to 3+63/64 0x5: Coded as 2-bit integer, 6-bit fraction + 1.0 Range from 1 to 4+63/64 0x6: Coded as 3-bit integer, 5-bit fraction Range from 0 to 7+31/32 0x7: Coded as 3-bit integer, 5-bit fraction + 1.0 Range from 1 to 8+31/32	RW	0x0

Bits	Field Name	Description	Type	Reset
0	ENABLE	<p>Enables/disables LSC</p> <p>0x0: Disables the module at the end of the current frame. Video data is transmitted without modification when LSC is disabled. The BUSY bit can be used to poll when access to SBL buffer can be used by the preview module.</p> <p>0x1: Enables the module. Module starts fetching the gain table as soon it is started. Firmware has to make sure it has been correctly initialized before starting the module. Data processing is only effective at the start of the next frame. Note that preview module dark frame subtract must be disabled because there is only one shared read port.</p>	RW	0x0

#### 1.6.4.33 CCDC LSC INITIAL

**Table 1-125. CCDC LSC INITIAL**

Address Offset		0x0000 009C																															
Physical Address		0x480B C69C																Instance		ISP_CCDC													
Description		LENS SHADING COMPENSATION INITIAL X/Y REGISTER																															
Type		RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED								Y								RESERVED								X									
Bits		Field Name										Description										Type				Reset							
31:22		RESERVED										Write 0s for future compatibility. Reads return zero.										RW				0x000							
21:16		Y										Y position, in pixels, of the first active pixel in reference to the first active paxel. Must be an even number.										RW				0x00							
15:6		RESERVED										Write 0s for future compatibility. Reads return zero.										RW				0x000							
5:0		X										X position, in pixels, of the first active pixel in reference to the first active paxel. Must be an even number.										RW				0x00							

#### 1.6.4.34 CCDC LSC TABLE BASE

**Table 1-126. CCDC LSC TABLE BASE**

[illegible]

#### 1.6.4.35 CCDC LSC TABLE OFFSET

**Table 1-127. CCDC\_LSC\_TABLE\_OFFSET**

<b>Address Offset</b>	0x0000 00A4		
<b>Physical Address</b>	0x480B C6A4	<b>Instance</b>	ISP_CCDC
<b>Description</b>	LENS SHADING COMPENSATION TABLE OFFSET REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								OFFSET																							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000
15:0	OFFSET	Defines the length, in bytes, of one row of the gain table. Gain table is 32-bit aligned, so this value must be a multiple of 4. Note that the row in memory must be longer or equal to what LSC uses.	RW	0x0000

## 1.6.5 ISP\_HIST Register Descriptions

### 1.6.5.1 HIST\_PID

**Table 1-128. HIST\_PID**

<b>Address Offset</b>	0x0000 0000		
<b>Physical Address</b>	0x480B CA00	<b>Instance</b>	ISP_HIST

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x00
23:16	TID	Peripheral identification: HIST MODULE	R	0x08
15:8	CID	Class identification: CAMERA ISP	R	0xFE
7:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x00

### 1.6.5.2 HIST\_PCR

**Table 1-129. HIST\_PCR**

<b>Address Offset</b>	0x0000 0004		
<b>Physical Address</b>	0x480B CA04	<b>Instance</b>	ISP_HIST
<b>Description</b>	PERIPHERAL CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																BUSY		ENABLE													

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000000
1	BUSY	HIST module busy. 0x0: Module is not busy. 0x1: Module is busy.	RW	0x0
0	ENABLE	HIST module enable. 0x0: Disable module 0x1: Enable module	RW	0x0

### 1.6.5.3 HIST\_CNT

**Table 1-130. HIST\_CNT**

Address Offset		0x0000 0008																													
Physical Address		0x480B CA08																													
Description		HISTOGRAM CONTROL REGISTER																													
Type		RW																													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																DAT SIZ	CLR	CFA	BINS		SOURCE	SHIFT									
Bits		Field Name		Description												Type		Reset													
31:9		RESERVED		Write 0s for future compatibility. Reads returns 0.												RW		0x000000													
8		DATSIZ		Input data width  0x0: The pixels are coded on more than 8 bits. 0x1: The pixels are coded on 8 bits.												RW		0x0													
7		CLR		Clear histogram data after read.  0x0: Don't clear the data after read. 0x1: Clear the data after read.												RW		0x0													
6		CFA		CFA pattern.  0x0: Bayer pattern. 0x1: Foveon pattern.												RW		0x0													
5:4		BINS		Number of bins.  0x0: 32 bins, REGIONS 0, 1, 2 and 3 are active. 0x1: 64 bins, REGIONS 0, 1, 2 and 3 are active. 0x2: 128 bins, REGIONS 0 and 1 are active. 0x3: 256 bins, REGION 0 is active.												RW		0x0													
3		SOURCE		Input source.  0x0: The input data comes from the CCDC module. 0x1: The input data comes from memory.												RW		0x0													
2:0		SHIFT		Shift value. The pixel data is right shifted before the binning operation. The shift value can vary from 0 to 7.												RW		0x0													

### 1.6.5.4 HIST\_WB\_GAIN

**Table 1-131. HIST\_WB\_GAIN**

<b>Address Offset</b>		0x0000 000C			
<b>Physical Address</b>		0x480B CA0C		<b>Instance</b>	ISP_HIST
<b>Description</b>		HISTOGRAM WHITE BALANCE GAIN REGISTER			
<b>Type</b>		RW			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WG00								WG01								WG02								WG03							

Bits	Field Name	Description	Type	Reset
31:24	WG00	White balance gain 00. The gain value is unsigned and in 3Q5 representation. It varies from 0 to 7.96875.	RW	0x20
23:16	WG01	White balance gain 01. The gain value is unsigned and in 3Q5 representation. It varies from 0 to 7.96875.	RW	0x20
15:8	WG02	White balance gain 02. The gain value is unsigned and in 3Q5 representation. It varies from 0 to 7.96875.	RW	0x20
7:0	WG03	White balance gain 03. The gain value is unsigned and in 3Q5 representation. It varies from 0 to 7.96875.	RW	0x20

### 1.6.5.5 HIST\_Rn\_HORZ

**Table 1-132. HIST\_Rn\_HORZ**

<b>Address Offset</b>	0x0000 0010 + (0x8 * n)	<b>Index</b>	n = 0 to 3
<b>Physical Address</b>	0x480B CA10 + (0x8 * n)	<b>Instance</b>	ISP_HIST
<b>Description</b>	REGION n HORIZONTAL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 1.6.6 ISP\_H3A Register Descriptions

### 1.6.6.1 H3A\_PID

**Table 1-139. H3A\_PID**

Address Offset								0x0000 0000																Instance								ISP_H3A							
Physical Address								0x480B CC00																															
Description								PERIPHERAL ID REGISTER																															
Type								R																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
RESERVED								TID								CID								RESERVED															
Bits		Field Name						Description										Type				Reset																	
31:24		RESERVED						Write 0s for future compatibility. Reads returns 0.										R				0x00																	
23:16		TID						Peripheral identification: H3A module.										R				0x08																	
15:8		CID						Class identification: CAMERA ISP										R				0xFE																	
7:0		RESERVED						Write 0s for future compatibility. Reads returns 0.										R				0x00																	

### 1.6.6.2 H3A\_PCR

**Table 1-140. H3A\_PCR**

Address Offset		0x0000 0004																Instance		ISP_H3A															
Physical Address		0x480B CC04																																	
Description		PERIPHERAL CONTROL REGISTER																																	
Type		RW																																	
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
AVE2LMT								RESERVED		BUSYAEAWB	AEW_ALAW_EN	AEW_EN	BUSYAF	FVMODE	RGBPOS				MED_TH				AF_MED_EN	AF_ALAW_EN	AF_EN										

Bits	Field Name	Description	Type	Reset
31:22	AVE2LMT	AE AWB saturation limit. All pixels in a block are compared to this limit. If one pixel is above the limit, the block is considered saturated.	RW	0x3FF
21:19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
18	BUSYAEAWB	AE AWB busy 0x0: AE AWB not busy 0x1: AE AWB busy	R	0x0
17	AEW_ALAW_EN	AE AWB A-Law enable 0x0: Disable AE AWB A-Law table. 0x1: Disable AE AWB A-Law table.	RW	0x0
16	AEW_EN	AE AWB enable 0x0: Disable AE AWB. 0x1: Enable AE AWB.	RW	0x0

Bits	Field Name	Description	Type	Reset
15	BUSYAF	AF busy 0x0: AF not busy. 0x1: AF busy.	R	0x0
14	FVMODE	Focus value accumulation mode 0x0: Sum mode. 0x1: Peak mode.	RW	0x0
13:11	RGBPOS	RGB pixel position in the AF windows 0x0: GR and GB as Bayer pattern. 0x1: RG and GB as Bayer pattern. 0x2: GR and BG as Bayer pattern. 0x3: RG and BG as Bayer pattern. 0x4: GG and RB as Bayer pattern. 0x5: RB and GG as Bayer pattern.	RW	0x0
10:3	MED_TH	Median filter threshold	RW	0xFF
2	AF_MED_EN	AF median filter enable 0x0: Disable autofocus median filter 0x1: Enable autofocus median filter	RW	0x0
1	AF_ALAW_EN	AF A-Law table enable 0x0: Disable autofocus A-Law table. 0x1: Enable autofocus A-Law table.	RW	0x0
0	AF_EN	AF enable 0x0: Disable autofocus 0x1: Enable autofocus	RW	0x0

### 1.6.6.3 H3A\_AFPAX1

**Table 1-141. H3A\_AFPAX1**

Address Offset		0x0000 0008																Instance		ISP_H3A											
Physical Address		0x480B CC08																													
Description		AF PAXEL CONFIGURATION																													
Type		RW																													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								PAXW								RESERVED								PAXH							
Bits		Field Name						Description																Type		Reset					
31:23		RESERVED						Write 0s for future compatibility. Reads returns 0.																RW		0x000					
22:16		PAXW						Paxel width. The paxel width is set by 2 x (PAXW+1). The paxel-width range varies from 2 to 256. The paxel width must be set to a minimum value of 16 pixels.																RW		0x00					
15:7		RESERVED						Write 0s for future compatibility. Reads returns 0.																RW		0x000					
6:0		PAXH						Paxel height. The paxel height is set by 2 x (PAXH+1). The paxel-height range varies from 2 to 256.																RW		0x00					

**Table 1-144. H3A\_AFIIRSH**

<b>Address Offset</b>	0x0000 0014	<b>Instance</b>	ISP_H3A
<b>Physical Address</b>	0x480B CC14		
<b>Description</b>	AF IIR HORIZONTAL START POSITION REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																IIRSH															

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
11:0	IIRSH	AF IIR horizontal start position. The range is 0 to 4095. When the horizontal position of a line equals this value the shift registers are cleared on the next pixel.	RW	0x000

### 1.6.6.7 H3A\_AFBUFST

**Table 1-145. H3A\_AFBUFST**

<b>Address Offset</b>	0x0000 0018	<b>Instance</b>	ISP_H3A

15:8		CID		Class identification: CAMERA ISP																R		0xFE													
7:0		RESERVED		Write 0s for future compatibility. Reads returns 0.																R		0x00													

### 1.6.7.2 PRV\_PCR

**Table 1-164. PRV\_PCR**

Address Offset		0x0000 0004																Instance		ISP_PREVIEW													
Physical Address		0x480B CE04																															
Description		PERIPHERAL CONTROL REGISTER All the fields in this register can be altered even when the PREVIEW module is busy. Changes take place only for the next frame.																															
Type		RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
DRK_FAIL	RESERVED		DCOR_METHOD	DCOREN	GAMMA_BYPASS	RESERVED		SCOMP_SFT		SCOMP_EN	SDRPORT	RSZPORT	YCPOS		SUPEN	YNENHEN	CFAFMT				CFAEN	NFEN	HMEDEN	DRKFCAP	DRKFEN	INVALAW	WIDTH	ONESHOT	SOURCE	BUSY	ENABLE		

Bits	Field Name	Description	Type	Reset
31	DRK_FAIL	Dark frame subtract fail status. Write 1 to clear this bit. Reset to zero for the next frame. When the error is triggered, dark frame subtract is abandoned for the current frame, dark frame subtract resumes for next frame (but bit is not cleared unless explicitly done by firmware).  0x0: No error 0x1: Error	RW	0x0
30:29	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
28	DCOR_METHOD	Defect correction method.  0x0: MinMax 0x1: MinMax2 (Couplet defect correction)	RW	0x0

Bits	Field Name	Description	Type	Reset
27	DCOREN	Defect correction enable This bit enables or disables the defect correction. The PRV_PCR.DCOR_METHOD and PRV_CDC_THRx registers must be configured for correct operation. 0x0: Disable defect correction 0x1: Enable defect correction	RW	0x0
26	GAMMA_BYPASS	Bypass, the output is set to the 8 MSB of the 10-bit input. 0x0: No bypass. 0x1: Bypass, the output is set to the 8 MSB of the 10-bit input.	RW	0x0
25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
24:22	SCOMP_SFT	Shading compensation shift value after multiplication. The right-shift range is 0 to 7.	RW	0x0
21	SCOMP_EN	Shading compensation enable instead of dark frame The 8-bit value loaded from memory is multiplied by the current pixel instead of subtracting it. Note that the dark frame subtract (DRKFEN) must be enabled in addition to this bit being active to perform shading compensation. 0x0: Disable. Dark frame subtract can be used. 0x1: Enable. Dark frame subtract cannot be used.	RW	0x0
20	SDRPORT	PREVIEW module memory output port enable. This bit enables or disables the data transfer from the PREVIEW module to the memory. 0x0: Disable 0x1: Enable	RW	0x1
19	RSZPORT	RESIZER module output port enable. This bit enables or disables the data transfer between the PREVIEW and RESIZER modules. Controls whether or not SDRAM output data is forwarded to the resizer input port. This control bit does not depend on the state of the former SDRPORT bit. Data is simultaneously written to SDRAM (if SDRPORT bit is set) while sending the same data to the resizer as input. Note that the CCDC is also capable of directly writing to the resizer input port. The CCDC setting takes precedence over the preview engine setting. 0x0: Disable 0x1: Enable	RW	0x0
18:17	YCPOS	(CRYCBY) Cr0(31:24) Y1(23:16) Cb0(15:8) Y0(7:0) 0x0: (YCRYCB) Y1(31:24) Cr0(23:16) Y0(15:8) Cb0(7:0) 0x1: (YCBYCR) Y1(31:24) Cb0(23:16) Y0(15:8) Cr0(7:0) 0x2: (CBYCRY) Cb0(31:24) Y1(23:16) Cr(15:8) Y0(7:0) 0x3: (CRYCBY) Cr0(31:24) Y1(23:16) Cb0(15:8) Y0(7:0)	RW	0x0
16	SUPEN	Color suppression. 0x0: Disable 0x1: Enable	RW	0x0
15	YNENHEN	Non-linear enhancer 0x0: Disable 0x1: Enable	RW	0x0

Bits	Field Name	Description	Type	Reset
14:11	CFAFMT	CFA format 0x0: Mode 0: conventional Bayer. 0x1: Mode 1: horizontal 2x downsample. 0x2: Mode 2: bypass CFA stage (RGB Foveon) 0x3: Mode 3: horizontal and vertical 2x downsample. 0x4: Mode 4: Fuji Honeycom movie mode sensor. 0x5: Mode5: bypass CFA stage (RRRR GGGG BBBB Foveon).	RW	0x0
10	CFAEN	CFA enable 0x0: Disable 0x1: Enable	RW	0x0
9	NFEN	Noise filter enable 0x0: Disable 0x1: Enable	RW	0x0
8	HMEDEN	Horizontal median filter enable. 0x0: Disable 0x1: Enable	RW	0x0
7	DRKFCAP	Dark frame capture enable. 0x0: Normal processing. 0x1: Capture dark frame.	RW	0x0
6	DRKFEN	Subtract dark frame enable. 0x0: Disable 0x1: Enable	RW	0x0
5	INVALAW	Inverse A-Law enable. 0x0: Disable 0x1: Enable	RW	0x0
4	WIDTH	Input data width selection. 0x0: 10-bit mode 0x1: 8-bit mode	RW	0x0
3	ONESHOT	One-shot mode selection. If this bit is set to 1, it is reset to 0 after the ENABLE bit is asserted. 0x0: Continuous mode (through the video port). 0x1: One shot mode.	RW	0x0
2	SOURCE	Input source selection. If this bit is set to 1, it is reset to 0 after the ENABLE bit is asserted. 0x0: Video port (through the CCDC) 0x1: Memory.	RW	0x0
1	BUSY	Busy bit. 0x0: PREVIEW module not busy. 0x1: PREVIEW module busy.	R	0x0
0	ENABLE	Enable bit. If the ONESHOT or SOURCE bit is 1, this bit is reset to 0 after it is asserted 0x0: PREVIEW module disabled. 0x1: PREVIEW module enabled.	RW	0x0

### 1.6.7.3 PRV\_HORZ\_INFO

**Table 1-165. PRV\_HORZ\_INFO**

<b>Bits</b>		<b>Field Name</b>						<b>Description</b>														<b>Type</b>				<b>Reset</b>					
31:28		RESERVED						Write 0s for future compatibility. Reads returns 0.														RW				0x00					
27:16		VERT						Output height.														RW				0x000					
15:12		RESERVED						Write 0s for future compatibility. Reads returns 0.														RW				0x00					
11:0		HORZ						Output (width in the horizontal direction) The maximum output width cannot be greater than 3312 pixels wide (1650 if downsampling greater than 2 is used with 7 filter taps) This value must be EVEN and the number of bytes written to SDRAM must be a multiple of 16-bytes if the vertical resizing factor is greater than 1x (upsizing)														RW				0x000					

#### 1.6.8.5 RSZ\_IN\_START

**Table 1-202. RSZ\_IN\_START**

<b>Address Offset</b>	0x0000 0010																																
<b>Physical Address</b>	0x480B D010																<b>Instance</b>	ISP_RESIZER															
<b>Description</b>	INPUT CONFIGURATION REGISTER This register must be used when the input pixel data comes from the PREVIEW module. must be set to 0 is the input pixel data comes from memory.																																
<b>Type</b>	RW																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED								VERT_ST								RESERVED								HORZ_ST									

Bits	Field Name	Description	Type	Reset
31:29	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
28:16	VERT_ST	Vertical start line. This field makes sense when the resizer obtains its input from the preview engine/CCDC When the resizer gets its input from SDRAM, this field must be set to 0	RW	0x0000
15:13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:0	HORZ_ST	Horizontal start pixel. Pixels are coded on 16 bits for YUV and 8 bits for color separate data. When the resizer gets its input from SDRAM, this field must be set to <= 15 for YUV 16-bit data and <= 31 for 8-bit color separate data Horizontal starting pixel value is in number of pixels if input is from SDRAM. If the input to the resizer is from CCDC/preview engine, this field must be programmed as follows: (1) Program this field using number of bytes (twice number of pixels). (2) Change the lowest bit to reflect start position in pixels (effectively change from a value 0 to a value 1 if required)	RW	0x0000

### 1.6.8.6 RSZ\_IN\_SIZE

**Table 1-203. RSZ\_IN\_SIZE**

Address Offset		0x0000 0014																Instance		ISP_RESIZER															
Physical Address		0x480B D014																																	
Description		INPUT SIZE REGISTER																																	
Type		RW

RESERVED				VERT												RESERVED				HORZ															
Bits	Field Name		Description																Type		Reset														
31:29	RESERVED		Write 0s for future compatibility. Reads returns 0.																RW		0x0														
28:16	VERT		Input height. The range is 0 to 4095 lines.																RW		0x0000														
15:13	RESERVED		Write 0s for future compatibility. Reads returns 0.																RW		0x0														
12:0	HORZ		Input width. The range is 0 to 4095 pixels.																RW		0x0000														

### 1.6.8.7 RSZ\_SDR\_INADD

**Table 1-204. RSZ\_SDR\_INADD**

<b>Address Offset</b>	0x0000 0018		<b>Instance</b>	ISP_RESIZER
<b>Physical Address</b>	0x480B D018			
<b>Description</b>	INPUT ADDRESS REGISTER This register must be set only if the input pixel data comes from memory.			
<b>Type</b>	RW			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR																															

Bits	Field Name	Description	Type	Reset
31:0	ADDR	32-bit input memory address. The 5 LSBs are forced to be zeros by the hardware to align on a 32-byte boundary; the 5 LSBs are read-only. This field must be programmed to be 0x0 if the resizer input is from preview engine/CCDC. * This field can be altered even when the resizer is busy. The change takes place only for the next frame. However, note that reading this register always gives the latest value.	RW	0x00000000

### 1.6.8.8 RSZ\_SDR\_INOFF

**Table 1-205. RSZ\_SDR\_INOFF**

<b>Address Offset</b>	0x0000 001C		<b>Instance</b>	ISP_RESIZER
<b>Physical Address</b>	0x480B D01C			
<b>Description</b>	INPUT OFFSET REGISTER This register must be set only if the input pixel data comes from memory.			
<b>Type</b>	RW			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																OFFSET															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
15:0	OFFSET	Memory offset for the input lines. The 5 LSBs are forced to be zeros by the hardware to align on a 32-byte boundary; the 5 LSBs are read-only. This field must be programmed to be 0x0 if the resizer input is from preview engine/CCDC. * This field can be altered even when the resizer is busy. The change takes place only for the next frame. However, note that reading this register always gives the latest value.	RW	0x0000

### 1.6.9.2 SBL\_PCR

**Table 1-242. SBL\_PCR**

<b>Address Offset</b>	0x0000 0004																																
<b>Physical Address</b>	0x480B D204																<b>Instance</b>	ISP_SBL															
<b>Description</b>	PERIPHERAL CONTROL REGISTER Note on the overflow bits: the overflow does not prevent the modules to make further requests. The only way to clear the overflow is to reset the bit. After an overflow, the data are corrupted and the application layer should disregard the data. No software reset is required after an overflow. If the overflow condition is cleared, the data continue to be acquired normally.																																
<b>Type</b>	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED								CCDCPRV_2_RSZ_OVF	CCDC_WBL_OVF	PRV_WBL_OVF	RSZ1_WBL_OVF	RSZ2_WBL_OVF	RSZ3_WBL_OVF	RSZ4_WBL_OVF	H3A_AF_WBL_OVF	H3A_AEAWB_WBL_OVF	RESERVED															

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
24	CCDCPRV_2_RSZ_OVF	CCDC/PRV to RESIZER input overflow This bit is set if the RESIZER input source is set to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of > 4x is required per frame. Therefore, the RESIZER needs to operate in two passes. In the first pass the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should only start after the second pass on the previous frame is complete. This bit indicated the failure status. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0
23	CCDC_WBL_OVF	CCDC Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0
22	PRV_WBL_OVF	PREVIEW Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0
21	RSZ1_WBL_OVF	RESIZER line 1 Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0
20	RSZ2_WBL_OVF	RESIZER line 2 Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0
19	RSZ3_WBL_OVF	RESIZER line 3 Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0
18	RSZ4_WBL_OVF	RESIZER line 4 Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0
17	H3A_AF_WBL_OVF	H3A AF Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0
16	H3A_AEAWB_WBL_OVF	H3A AE AWB Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. 0x0: No overflow 0x1: Overflow	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

## **2D/3D Graphics Accelerator (SGX)**

---

---

---

This chapter describes the 2D/3D graphics accelerator (SGX) for the device.

---

**Note:** SGX is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this feature.

---

---

**Note:** The SGX is an instantiation of the POWERVR™ SGX from Imagination Technologies™ Ltd. This document contains materials that are Copyright © 2003-2007 Imagination Technologies Ltd. ## 1.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the SGX core from Imagination Technologies. SGX is a new generation of programmable PowerVR graphic cores. Targeted applications include feature phones, PDA, hand-held games, PND (portable navigation devices), MID (mobile Internet devices), automotive, and medical instrumentation.

Figure 1-1 shows the SGX subsystem in the device.

**Figure 1-1. Graphics Accelerator Highlight**

sgx-001

The SGX graphics accelerator efficiently processes a number of various multimedia data types concurrently:

- Pixel data
- Vertex data

This is achieved using a multithreaded architecture using two levels of scheduling and data partitioning enabling zero overhead task switching.

The SGX subsystem is connected by a 64-bit master and a 32-bit slave interface to the L3 interconnect.

### 1.1.1 PowerVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programmable GPU functions
- Tile-based architecture
- Universal scalable shader engine (USSE) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OGL2.0

- Industry standard API support - OpenGL-ES 1.1 and 2.0, OpenVG 1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- PowerVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- 2D operations via the 3D pipeline

### 1.1.2 SGX 3D features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
  - Cube map
  - Projected textures
  - 2D textures
  - nonsquare textures
- Texture formats:
  - RGBA 8888,565,1555
  - Monochromatic 8, 16, 16f, 32f, 32int
  - Dual channel, 8:8, 16:16, 16f:16f
  - Compressed textures PVR-TC1, PVR-TC2, ETC1
  - Programmable support for all YUV formats
- Resolution support:
  - Frame buffer maximum size = 2048 x 2048
  - Texture maximum size = 2048 x 2048
- Texture filtering:
  - Bilinear, tri-linear, anisotropic
  - Independent minimum and maximum control
- Anti-aliasing:
  - 4x multisampling
  - Up to 16x full scene anti-aliasing
  - Programmable sample positions
- Indexed primitive list support
  - Bus mastered
- Programmable vertex DMA
- Render to texture:
  - Including twiddled formats
  - Auto MipMap generation
- Multiple on-chip render targets (MRT). Note: Performance is limited when the on-chip memory is not available.

### 1.1.3 Universal Scalable Shader Engine – Key Features

The (USSE) is the engine core of the PowerVR SGX architecture and supports a broad range of instructions.

- Single programming model:

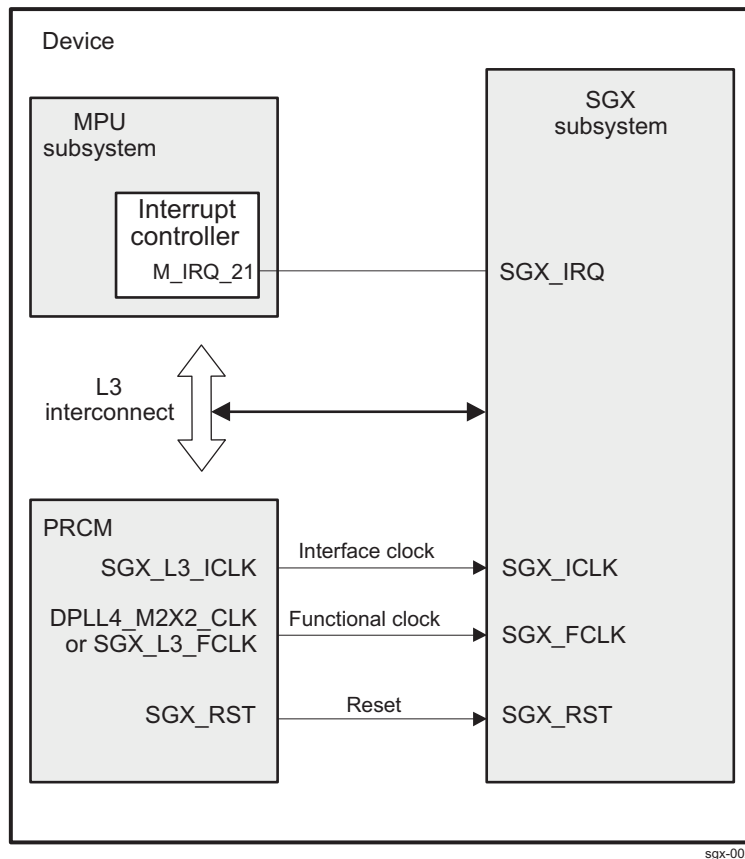

- Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
- Zero-cost swapping in, and out, of threads
- Cached program execution model
- Dedicated pixel processing instructions
- Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
  - 32-bit IEEE float
  - 2-way 16-bit fixed point
  - 4-way 8-bit integer
  - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
  - Subroutine calls
  - Loops
  - Conditional branches
  - Zero-cost instruction predication
- Procedural geometry:
  - Allows generation of primitives
  - Effective geometry compression
  - High-order surface support
- External data access:
  - Permits reads from main memory using cache
  - Permits writes to main memory
  - Data fence facility
  - Dependent texture reads

## 1.2 SGX Integration

Figure 1-2 highlights the SGX subsystem integration in the device.

**Figure 1-2. SGX Subsystem Integration**

### 1.2.1 Clocking, Reset, and Power-Management Scheme

#### 1.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX\_ICLK) and a functional clock (SGX\_FCLK). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device. The SGX clock tree is depicted in the *SGX Power Domain Clocking Scheme* section in the *Power, Reset, and Clock Management* chapter.

**Table 1-1. Clock Descriptions**

Signal Name	I/O <sup>(1)</sup>	Description
SGX_FCLK	I	Functional clock (two possible clock sources) -> Functional clock domain
SGX_ICLK	I	Interface clock (L3 interconnect clock domain) -> Interface clock domain

<sup>(1)</sup> I = Input, O = Output,

- The SGX\_ICLK interface clock manages the data transfer on the L3 master and slave ports. The source of SGX\_ICLK is the PRCM clock (SGX\_L3\_ICLK), which belongs to the SGX clock domain and runs at the L3 interconnect clock speed. The SGX\_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see *Power, Reset, and Clock Management* chapter.  
When no longer required by the SGX subsystem, SGX\_ICLK can be disabled by software at the PRCM level by setting the PRCM.CM\_ICLKEN\_SGX[0] EN\_SGX bit to 0. For more information, see

SGX Power Domain Clock Controls section in the *Power, Reset, and Clock Management* chapter.

---

**Note:** SGX\_ICLK is cut only if the SGX is ready to go into idle state. For more information, see *Power, Reset, and Clock Management* chapter.

---

- SGX\_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX and 3D domain clock signals.

The source of SGX\_FCLK is either the PRCM clock (SGX\_L3\_FCLK, which is derived from SGX\_ICLK) or the peripheral DPLL clock DPLL4\_M2X2\_CLK as depicted in the *SGX Power Domain Clocking Scheme* section of the *Power, Reset, and Clock Management* chapter. Selection is made at the PRCM level by setting the PRCM.CM\_CLKSEL\_SGX[2:0] CLKSEL\_SGX bit field. A divider of 3, 4, or 6 is applied to the SGX\_FCLK frequency with regard to the PRCM SGX\_L3\_FCLK frequency. By default the SGX\_FCLK clock is SGX\_L3\_FCLK / 3.

Whether SGX\_FCLK is provided by SGX\_L3\_FCLK or DPLL4\_M2X2\_CLK, its gating depends on the PRCM.CM\_FCLKEN\_SGX[1] EN\_SGX bit. Clearing this bit to 0 indicates that both SGX clocks are no longer needed and can be cut at the PRCM level, if the module is ready to enter the idle state. For more information, see the *SGX Power Domain* section in the *Power, Reset, and Clock Management* chapter.

### 1.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX\_RST signal in the SGX\_RST domain. Software controls the release of SGX\_RST using the PRCM.RM\_RSTCTRL\_SGX[0] SGX\_RST bit.

### 1.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See the *Power, Reset, and Clock Management* chapter, for additional information about the SGX power domain.

As described in [Section 1.2, SGX Integration](#), the SGX subsystem receives two clock signals from the PRCM module. The functional clock is either a division of the interface clock with a ratio of 1:3, 1:4, or 1:6, or a 96-MHz clock issued from a DPLL4. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see the *Power, Reset, and Clock Management* chapter.

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains.

## 1.2.2 Hardware Requests

### 1.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX\_IRQ) to the MPU subsystem interrupt controller mapped on M\_IRQ\_21.

## 1.3 SGX Functional Description

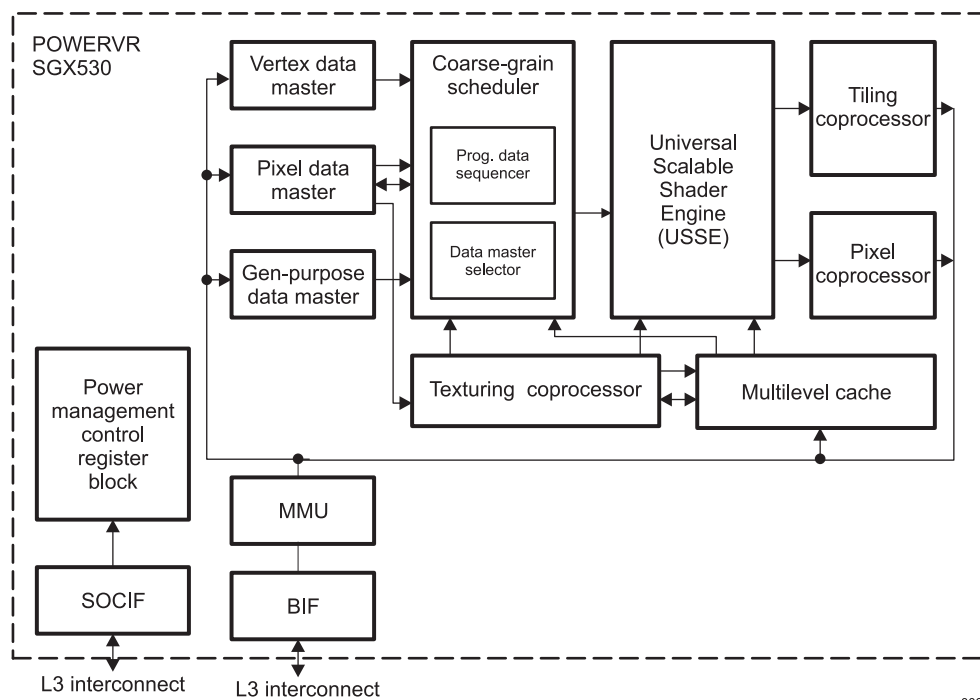

### 1.3.1 SGX Block Diagram

The SGX subsystem is based on the PowerVR SGX cores from Imagination Technologies. The architecture uses both programmable and hard coded pipelines to perform various processing tasks required in 2D and 3D. The SGX architecture comprises the following elements:

- Coarse grain scheduler
  - Programmable Data Sequencer (PDS)
  - Data Master Selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 1-3 shows a block diagram of the SGX cores.

**Figure 1-3. SGX Block Diagram**

### 1.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the PowerVR SGX Architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an input control stream, which contains triangle index data, and state data. The state data indicates the PDS program, size of the vertices and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.
- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile which allows for optimum efficiency within each pipe due to locality of data. For each task it determines the amount of resource required within the USSE. It merges this with the state address and issues a request for execution on the USSE to the DMS.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbitrator/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration is performed between the three data streams; any required texture decompression is also performed.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests into the multilevel cache. Data returned from the cache are then formatted according to the texture format selected and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing both the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer, and the USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

## 1.4 SGX Registers

[Table 1-2](#) describes the SGX memory mapping in the device.

**Table 1-2. Instance Summary**

Module Name	Start Address	End Address	Size
SGX	0x5000 0000	0x5000 FFFF	64K bytes

### 1.4.1 SGX Register Mapping Summary

#### CAUTION

The SGX registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

### 1.4.2 SGX Register Description

For more information about register descriptions, contact your TI representative.

## 1.5 Revision History

Table 1-3 lists the changes made since the previous version of this document.

## 1.1 IVA2.2 Subsystem Overview

The device includes the high-performance Texas Instruments image video and audio accelerator (IVA2.2), based on the TMS320DMC64X+ VLIW digital signal processor (DSP) core.

The internal architecture is an assembly of the following components:

- High-performance TI DSP (TMS320DMC64X+) integrated in a megacell, including local L1/L2 cache and memory controllers
- L1 RAM and L2 RAM and ROM
- Video hardware accelerator
- Dedicated enhanced data memory access (EDMA) engine to download/upload data from/to memories and peripherals external to the sub-chip
- Dedicated memory management unit (MMU) for accessing level 3 (L3) interconnect address space
- Local interconnect network
- Dedicated modules SYSC and WUGEN in charge of power management, clock generation, and connection to the power, reset, and clock manager (PRCM) module

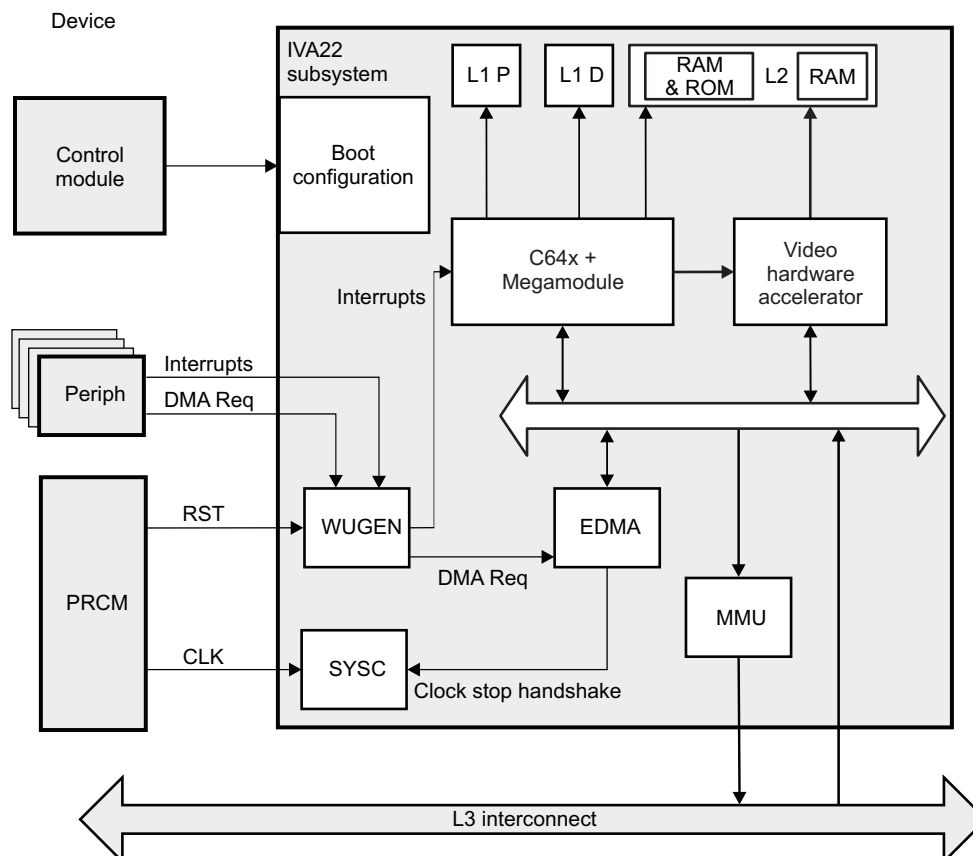

For information about C64x to C64x+ core migration, see the *TMS320C64x to TMS320C64x+ CPU Migration Guide* application note [SPRAA84A](#).

---

**Note:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

---

[Figure 1-1](#) shows the IVA2.2 subsystem top-level architecture.

**Figure 1-1. IVA2.2 Subsystem Highlight**

### 1.1.1 IVA2.2 Subsystem Key Features

The IVA2.2 subsystem has the following main features:

- 32-bit fixed-point media processor
- VLIW architecture based on programmable enhanced version of C64x DSP core
- 8 instructions/cycle, 8 execution units:
  - Optimized instruction set for video and image processing
  - Eight 8 x 8 or 16 x 16 MAC per cycle
  - Eight SAD per cycle
  - Eight interpolations (a + b + 1) >> 1 per cycle
  - Two (32-bit x 32-bit > 64-bit) multiply operations per cycle
- Low-power processor and megacell:
  - Dynamically mixed 32-bit and 16-bit instruction sets
  - Software pipelined loop (SPLOOP) instruction buffer
  - Separate power domain
  - Supported multiple power-down states
- 2-level memory subsystem hierarchy:
  - L1P (program):
    - 32KB direct-mapped cache-32-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
  - L1D (data):
    - 32KB 2-way set associative cache-64-byte cache line, configurable as cache or

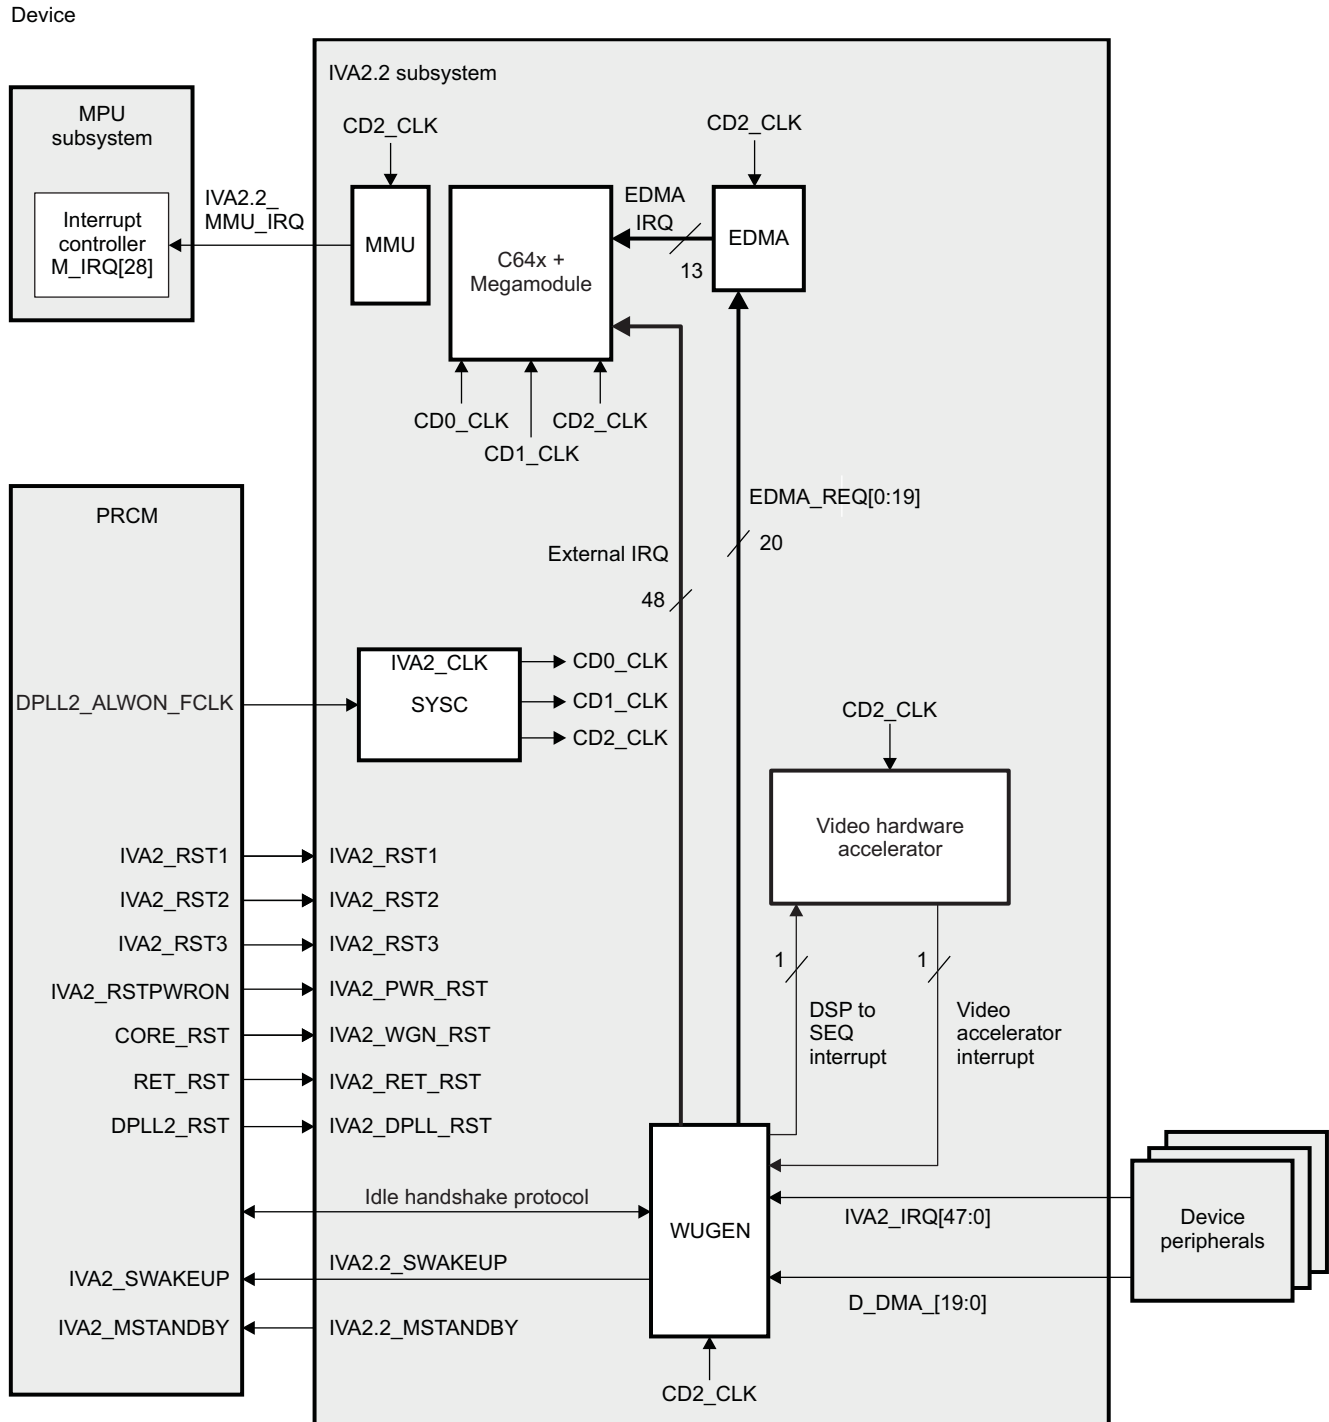

- memory-mapped (possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
  - 48-KB memory-mapped SRAM
- L2 (program and data):
  - 64KB 2-way set associative cache-128-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/64KB memory, 32KB/32KB, or 64KB/0KB)
  - 32-KB memory-mapped SRAM
  - 16-KB ROM
- Video hardware accelerator
- Private direct memory access (DMA) controller:
  - 128 logical channels
  - 1D/2D addressing
  - Chaining capability
  - Fully pipelined, two 64-bit read ports, two 64-bit write ports
  - Single-access 32-byte or 64-byte incrementing bursts
- Level 1 (L1) interrupt controller
- Local IVA digital phase-locked loop (DPLL) supplying IVA subsystem clocking
- 32-entry MMU for seamless integration in high-level operating system (OS) environment
- IVA2.2 system interfaces:
  - 64-bit L3 port shared for external memory accesses:
    - Multithreaded link shared by DSP core and DMA accesses
    - Interface with the L3 interconnect that can be synchronous or asynchronous for clock decoupling between IVA2.2 and L3
    - Incrementing burst support
    - Critical line first, to reduce line-fetch latency to the processor
  - Host port interface (HPI) for MMU programming and access to IVA2.2 internal memories. Can be synchronous or asynchronous.
  - System interfaces: clocking, power management
- C-friendly environment (state-of-the-art C-compiler for VLIW architecture)
- Texas Instruments low-overhead DSP-BIOS operating system

## 1.2 IVA2.2 Subsystem Integration

IVA hardware accelerators are not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this feature.

[Figure 1-2](#) shows IVA2.2 subsystem integration in the device.

Figure 1-2. IVA2.2 Subsystem Integration

## 1.2.1 Clocking, Reset, and Power-Management Scheme

### 1.2.1.1 Clocks

#### 1.2.1.1.1 IVA2.2 Clocks

The IVA2.2 subsystem receives one single-clock signal (DPLL2\_ALWON\_FCLK) from the PRCM.

**Note:** When the IVA2.2 subsystem does not require an internal clock, the internal clocks can be disabled at the PRCM level by setting the PRCM.CM\_FCLKEN\_IVA2 EN\_IVA2 bit to 0.

From this clock (DPLL2\_ALWON\_FCLK) and by using the DPLL2 module in the IVA2.2, three internal clocks are generated by the IVA2.2 system control module (SYSC):

- CD0\_CLK: Fastest IVA2.2 subsystem functional clock, dedicated to the DSP. Its frequency can be adjusted at the PRCM level by setting the PRCM.CM\_CLKSEL1\_PLL\_IVA2 and PRCM.CM\_CLKSEL2\_PLL\_IVA2 registers.
- CD1\_CLK: Divide-by-two of the CD0\_CLK clock
- CD2\_CLK: Divide-by-two of the CD0\_CLK clock

Generation of these three clocks is handled internally to the IVA2.2 subsystem by the SYSC module under direct control of the PRCM.

Table 1-1 lists the clock domains in the IVA2.2 subsystem and shows the roles of the clocks.

**Table 1-1. IVA2.2 Internal Clock**

<b>CD0</b>	CD0_CLK	DSP core + PMC + DMC
<b>CD1</b>	CD1_CLK	UMC + power-down + interrupt controller
<b>CD2</b>	CD2_CLK	EMC + IDMA + C64x + Megamodule external interfaces + local interconnect + EDMA + MMU

**Note:** The internal clocks can be shut down by the PRCM module after the handshake protocol is complete. To configure the PRCM so that internal clocks are hardware-supervised, set the PRCM.CM\_AUTOIDLE\_PLL\_IVA2[2:0] AUTO\_IVA2\_DPLL field to 0x1. For more information, see the *Power, Reset, and Clock Management* chapter.

#### CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

### 1.2.1.2 Resets

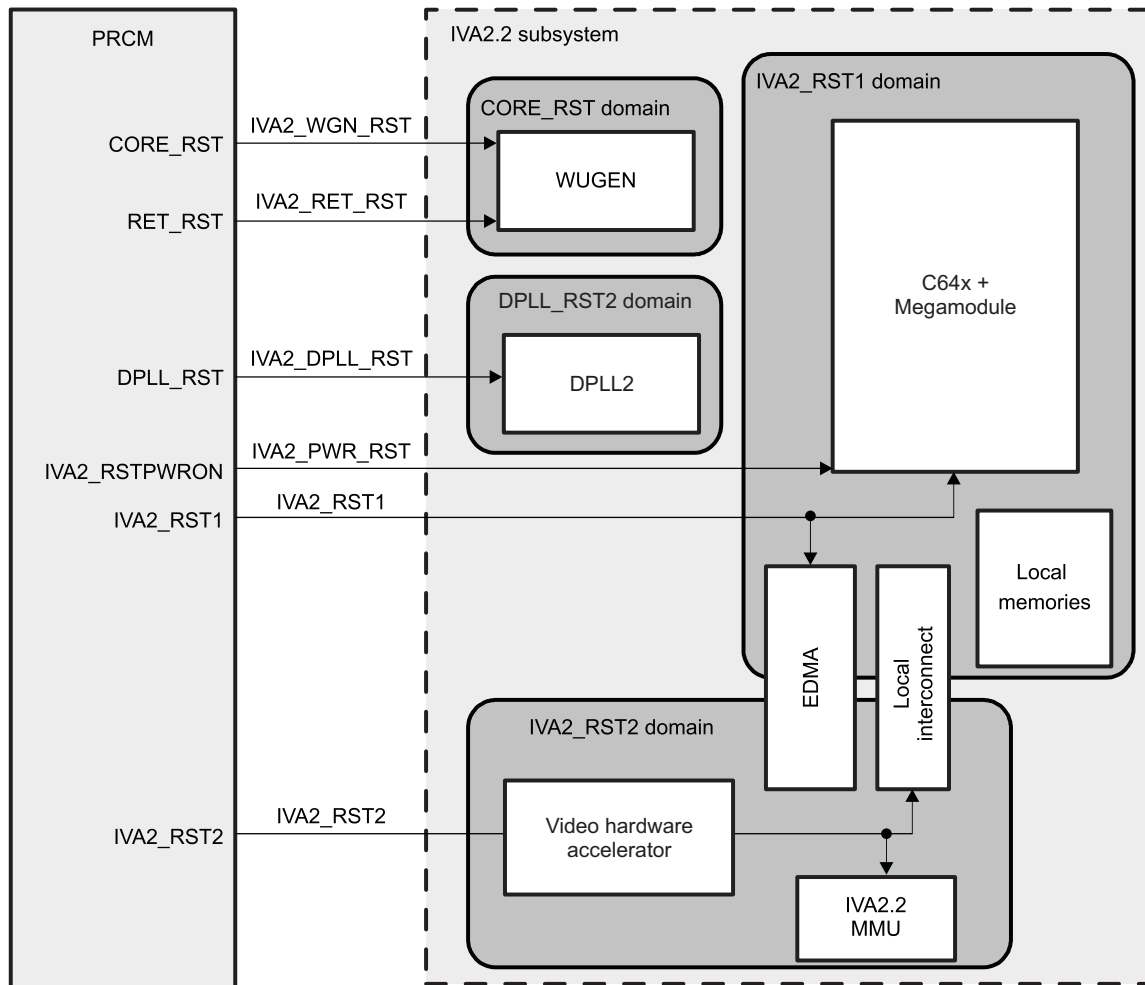

#### 1.2.1.2.1 Hardware Resets

Figure 1-3 shows the seven hardware input reset signals at the boundary of the IVA2.2 subsystem:

- IVA2\_RST1, connected to the C64x + Megamodule and EDMA modules
- IVA2\_RST2, connected to the MMU and the local interconnect
- CORE\_RST, connected to the IVA2.2 subsystem wake-up generator (WUGEN) module
- RET\_RST, connected to the subsystem WUGEN retention logic to reset registers that keep their value across a warm reset sequence
- IVA2\_RSTPWON, which performs a power-on initialization of IVA2.2 logic

- DPLL2\_RST, connected to the DPLL2 module

**Figure 1-3. IVA2.2 Subsystem Resets**

After chip power on, the IVA2.2 subsystem is kept under reset and only the DPLL2\_RST and the RET\_RST are released from reset. Then only the WUGEN is released from reset, as part of the core domain. The IVA2.2 remains under reset until the microprocessor unit (MPU) clears the PRCM.RM\_RSTCTRL\_IVA2[1] RST2\_IVA2 bit. On this action, the PRCM switches on the IVA2.2 power domain, sets the clocks back, and releases the power-on reset. When the IVA2.2 power-on sequence completes (hardware handshake), the PRCM releases the IVA2\_RST2 reset. At this stage, the C64x + Megamodule is kept under reset (unless the MPU also cleared the PRCM.RM\_RSTCTRL\_IVA2[0] RST1\_IVA2 bit); the MPU can upload some code and data in the C64x+ memory. When the MPU has uploaded the code in the C64x+ memory, the MPU clears the RST1\_IVA2 bit, releasing the C64x + Megamodule from reset.

The MPU can apply a software reset to the IVA2.2. For a software reset to be safe, the IVA2.2 must be in clock-off mode (DSP in idle mode with clocks shut down by the PRCM; for information about the clock-off state transition, see [Section 1.4.7.3, Power-Down and Wake-Up Management](#).) For instance, the MPU can use a mailbox interrupt to ask the IVA2.2 to go to IDLE state. In that case, only IVA2\_RST1 and/or IVA2\_RST2 and/or IVA2\_RST3 are applied, depending on which bits are set, and CORE\_RST and IVA2\_RSTPWON are never applied.

The IVA2.2 can also program the PRCM to go to OFF state automatically when the IVA2.2 is idle. Then, in response to a wake-up event (for example, an interrupt), the PRCM can switch on the IVA2.2 power domain, set the clocks back, and release the power-on reset. When the IVA2.2 power-on sequence completes (hardware handshake), the PRCM releases the IVA2\_RST1 and IVA2\_RST2 resets (RST1 and RST2 SW bits are assumed to be clear). CORE\_RST can be applied only if the device is coming out of CHIP OFF state (CORE power domain also in OFF state). In this case, CORE\_RST is released at the same time as the IVA power-on reset.

For some detected severe issues (security, watchdog) or if the user applies an external system reset, the IVA2.2 can receive a warm reset. IVA2\_RST1, IVA2\_RST2, DPLL\_RST, RET\_RST, and CORE\_RST are applied. When the warm reset source is released, IVA2\_RST1, IVA2\_RST2, and CORE\_RST are released. Power-on reset is not applied in this case.

The DPLL and retention logic resets (IDPLL\_RST and RET\_RST) are activated only on whole-device under reset and on power up from core retention.

### 1.2.1.2.2 Software Resets

IVA2.2 subsystem reset signals are sourced from the PRCM module. Some modules of the DSP subsystem can also be reset by software control.

The IVA2\_RST1 signal maps to the PRCM.RM\_RSTCTL\_IVA2\_RST1\_IVA2 bit and the IVA2\_RST2 signal maps to the PRCM.RM\_RSTCTL\_IVA2\_RST2\_IVA2 bit in the PRCM register RM\_RSTCTRL\_IVA2. Writing these three bit fields lets the software reset the IVA2.2 subsystem.

---

**Note:** Software reset can be applied only while the IVA2.2 subsystem is in clock-off mode.

---

The WUGEN reset signal (CORE\_RST) is reset with the CORE power domain, which is reset at the occurrence of either global cold or global warm reset events. For more information about global reset sources, see the *Power, Reset, and Clock Management* chapter.

For more information about software resets, see [Section 1.4.7.2, Reset Management](#).

### 1.2.1.3 Power Domain

The IVA2.2 subsystem comprises three power domains that can be shared with other subsystems at the chip level (see [Figure 1-4](#)):

- DSP power domain: Everything specified in the IVA2.2 subsystem, except the wake-up generator
- CORE power domain: Includes the WUGEN
- DPLL2 power domain: Includes the DPLL2

Figure 1-4. IVA2.2 Power Domain

100-004

The DSP power domain can be powered off if the CORE power domain is powered on. The PRCM ensures that the DSP power domain is always powered off when the CORE power domain is powered off.

The CORE power domain includes several other system-level components of the device. The WUGEN module is included in the CORE power domain to enable the powered-off DSP subsystem to be awakened after receiving an interrupt, a DMA request, or an L3 slave port access.

When the device enters off mode, the PRM asserts a signal that is distributed to the DPLL to safely isolate the DPLL cell and to set the DPLL cell in sleep mode to reduce power consumption.

Memory voltage can be reduced locally when memory is not being used, to reduce memory leakage:

- If IVA2.2 is not active, this is controlled by the PRCM.PM\_PWSTCTRL\_IVA2 register by setting the MEMONSTATE and/or MEMRETSTATE bit fields.

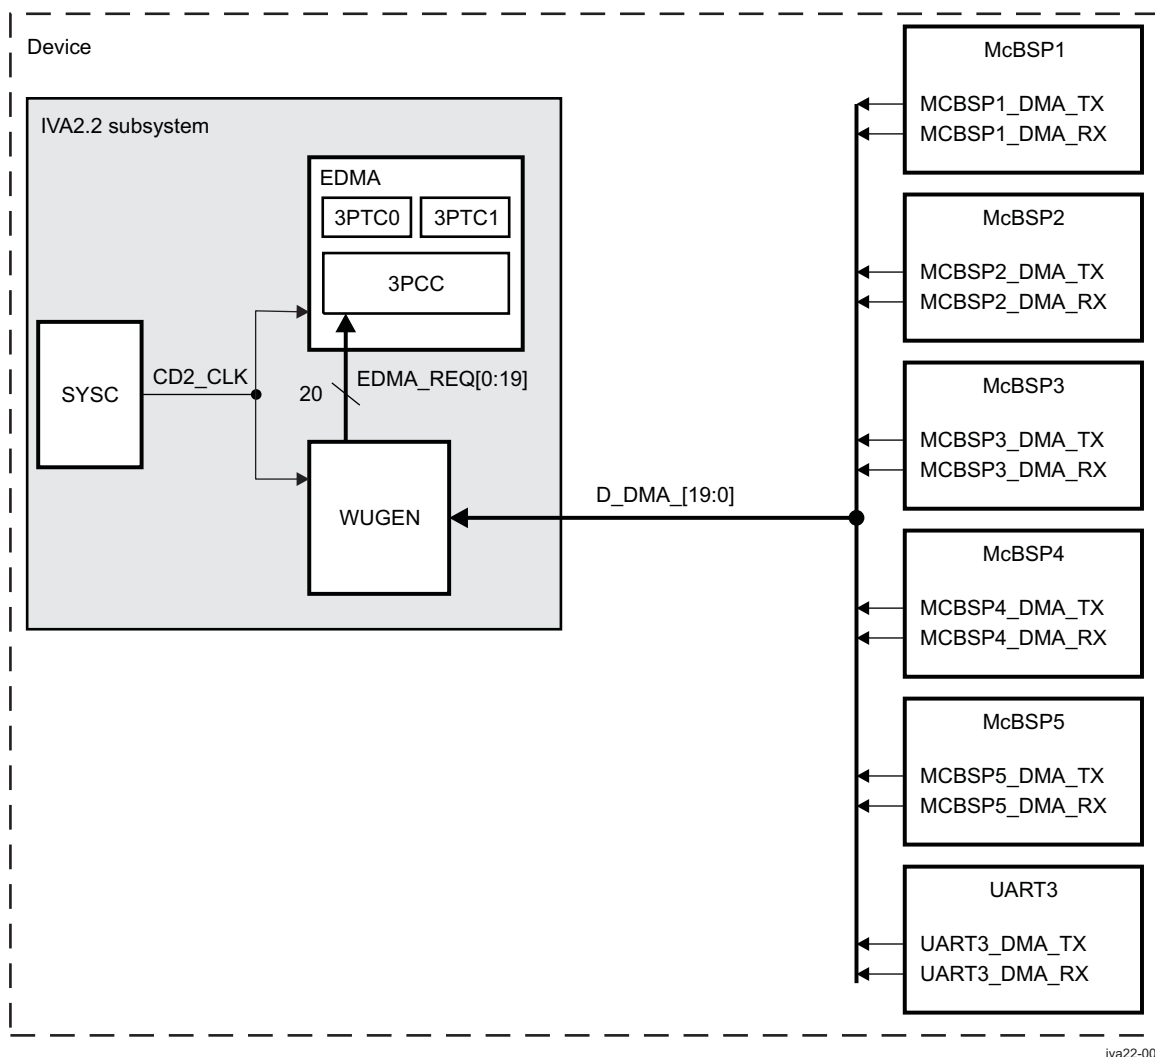

For a detailed description of power domains and controls in the device, see the *Power, Reset, and Clock Management* chapter.

## 1.2.2 Hardware Requests

### 1.2.2.1 DMA Requests

The IVA2.2 subsystem receives 14 DMA requests from specific peripherals, such as the McBSP module and the UART module (see [Figure 1-5](#)).

**Figure 1-5. IVA2.2 EDMA Requests**

For a description of the EDMA controller, see [Section 1.3.2.1, EDMA](#).

[Table 1-2](#) lists EDMA request mappings to the IVA2.2 subsystem EDMA controller.

**Table 1-2. IVA2.2 Subsystem EDMA Request Mappings**

DMA	Source	Description
D_DMA_0	MCBSP1_DMA_TX	MCBSP module 1 - transmit request
D_DMA_1	MCBSP1_DMA_RX	MCBSP module 1 - receive request
D_DMA_2	MCBSP2_DMA_TX	MCBSP module 2 - transmit request
D_DMA_3	MCBSP2_DMA_RX	MCBSP module 2 - receive request
D_DMA_4	MCBSP3_DMA_TX	MCBSP module 3 - transmit request
D_DMA_5	MCBSP3_DMA_RX	MCBSP module 3 - receive request
D_DMA_6	MCBSP4_DMA_TX	MCBSP module 4 - transmit request

**Table 1-2. IVA2.2 Subsystem EDMA Request Mappings (continued)**

DMA	Source	Description
D_DMA_7	MCBSP4_DMA_RX	MCBSP module 4 - receive request

D_DMA_15	Reserved	
D_DMA_16	Reserved	
D_DMA_17	Reserved	
D_DMA_18	Reserved	
D_DMA_19	Reserved	

**Note:** All EDMA requests are shared DMA requests; they are also mapped on the system DMA (sDMA). For more information, see the *DMA* chapter.

For more information about EDMA request management, see [Section 1.4.3.3, Programming an EDMA Transfer](#).

### 1.2.2.2 Interrupt Requests

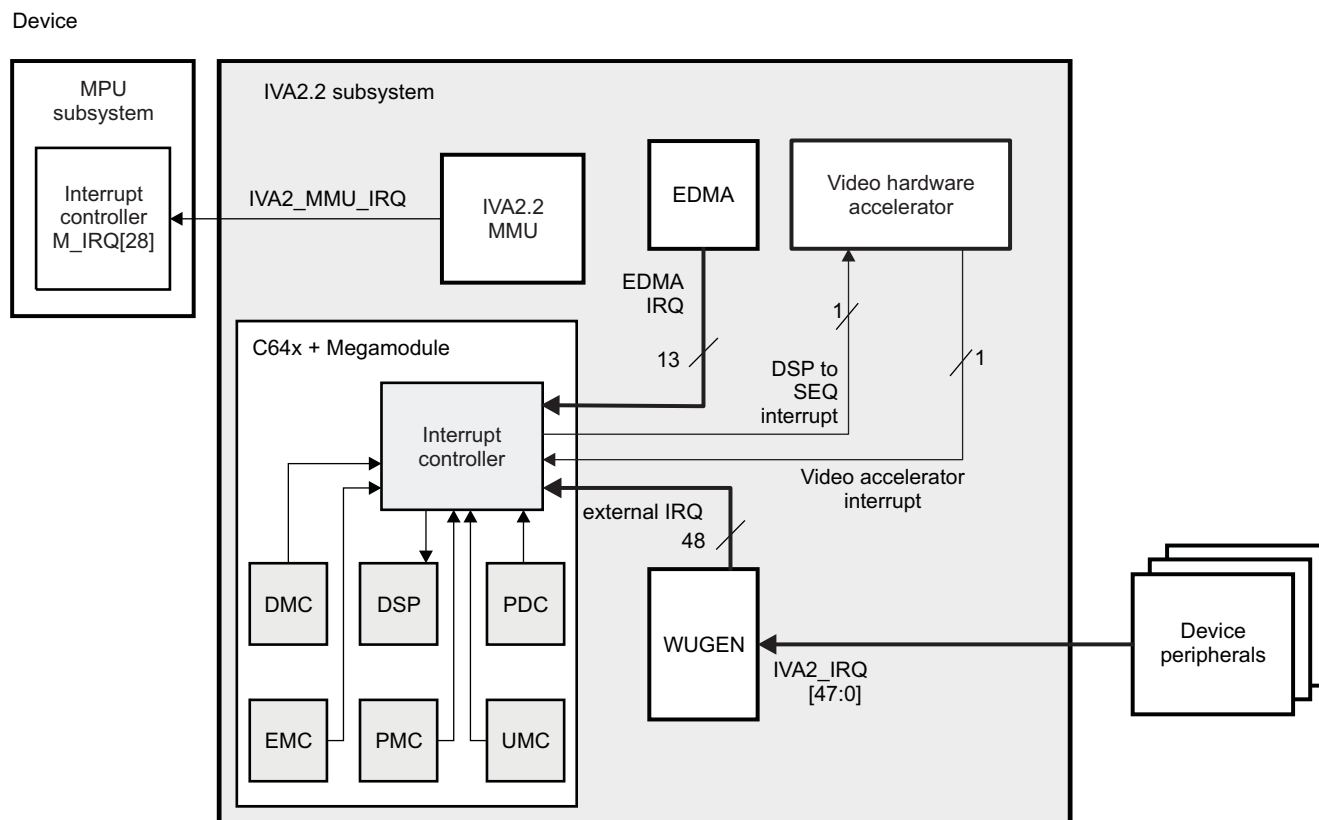

The IVA2.2 subsystem manages three types of interrupts (see [Figure 1-6](#)):

- Internal interrupts: Requests generated by modules in the IVA2.2 subsystem or in the C64x + Megamodule included in the IVA2.2 subsystem
- External interrupts: Requests generated by peripherals external to the IVA2.2 subsystem, like SPI, display subsystem, or camera subsystem. Peripherals that generate interrupts at the IVA2.2 level use the IVA2\_IRQ[47:0] input lines of the IVA2.2 subsystem.
- MMU interrupt: The IVA2.2 MMU can generate an interrupt to an external host outside the IVA2.2 subsystem. As shown in [Figure 1-2](#), the interrupt line of the MMU, IVA2\_MMU\_IRQ, is connected to M\_IRQ\_28 of the MPU subsystem interrupt controller.

For more information about the functionality of the IVA2.2 MMU, see [Section 1.3, IVA2.2 Subsystem Functional Description](#).

To manage and expand the interrupt capabilities of the C64x + Megamodule (internal and external interrupt requests), the IVA2.2 subsystem includes two levels of interrupt control (see [Figure 1-6](#)):

- One interrupt controller (INTC), integrated in the C64x + Megamodule. This module controls all interrupt requests (internal and external) except the MMU interrupt.  
For more information about the INTC, see [Section 1.3.1.6, Memory Protection Overview](#).
- One WUGEN: Responsible at the IVA2.2 subsystem level for detecting wake-up events (interrupts, DMA requests, and slave port access) when the IVA2.2 is powered down. The WUGEN also handles formatting interrupts from device peripherals to the C64x + Megamodule INTC.

**Figure 1-6. IVA2.2 Interrupt Management**

In addition to interrupt sources internal to the IVA2.2 subsystem, several interrupt sources coming from device peripherals are connected to the C64x + Megamodule INTC, but not directly.

These external interrupt sources are first resynchronized in the WUGEN module, synchronously with the CD2 clock domain clock (CD2\_CLK). Then the resynchronized versions are connected to the INTC.

Table 1-3 lists the global interrupt mappings of the IVA2.2 subsystem.

**Table 1-3. IVA2.2 Interrupt Mappings**

EVT	Interrupts/Events	IVA2.2 Pin Name	Interrupt Source	Interrupt Description
0	EVT0	N/A (internal)	GEM INT CTL	Output of event combiner 0, for events 4-31
1	EVT1	N/A (internal)	GEM INT CTL	Output of event combiner 1, for events 32-63
2	EVT2	N/A (internal)	GEM INT CTL	Output of event combiner 2, for events 64-95
3	EVT3	N/A (internal)	GEM INT CTL	Output of event combiner 3, for events 96-127

127	EMC_BUSERR	N/A (internal)	GEM EMC	BUSERR interrupt

<sup>(1)</sup> EVT94 is used by the DSP to generate an interrupt to the sequencer by means of the HOST\_MBX in the SEQ\_IRQSTATE register.

The interrupts generated by the WUGEN module (interrupts from device peripherals) are programmable using a set of registers accessible by the user.

Events related to these external interrupts can be masked by writing to the IVA2.WUGEN\_MEVTSET0 or IVA2.WUGEN\_MEVTSET1 registers. The interrupts can also be individually unmasked by using the IVA2.WUGEN\_MEVTCLR0 or IVA2.WUGEN\_MEVTCLR1 registers. By default (after power on), these external interrupts are masked in WUGEN.

All other interrupts are directly managed by the IVA2.2 DSP INTC, and the DSP registers are set. For information about the DSP INTC, see the documents listed in [Section 1.3.1.8, Other DSP Reference Documents](#).

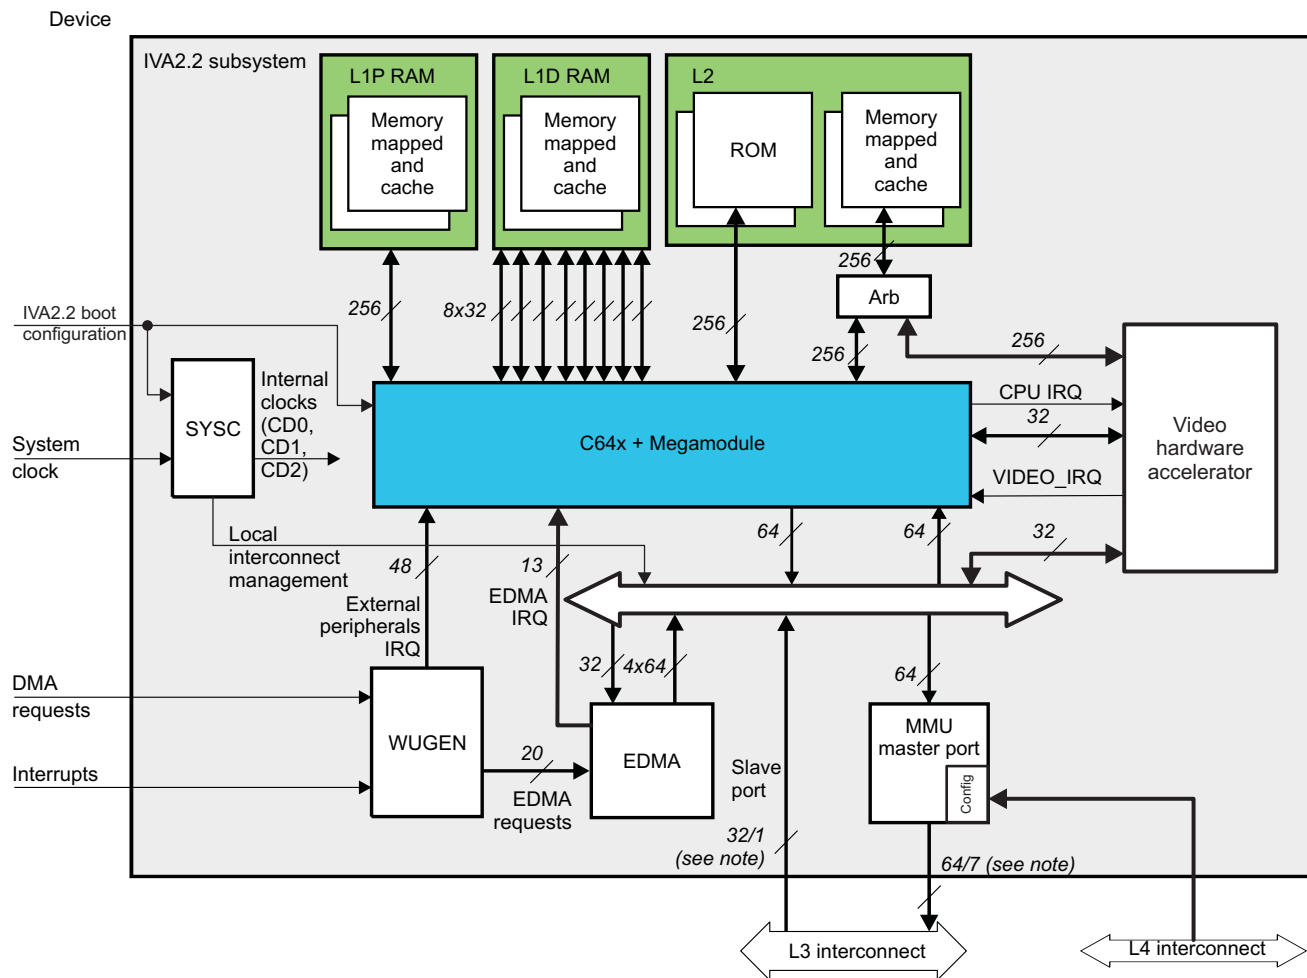

### 1.3 IVA2.2 Subsystem Functional Description

IVA hardware accelerators are not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this feature.

The IVA2.2 subsystem is composed of a C64x + Megamodule coupled with several submodules that enable its integration in the device architecture. The IVA2.2 subsystem provides one slave port and one master port; both ports are connected to the L3 interconnect.

Figure 1-7 is a block diagram of the IVA2.2 subsystem.

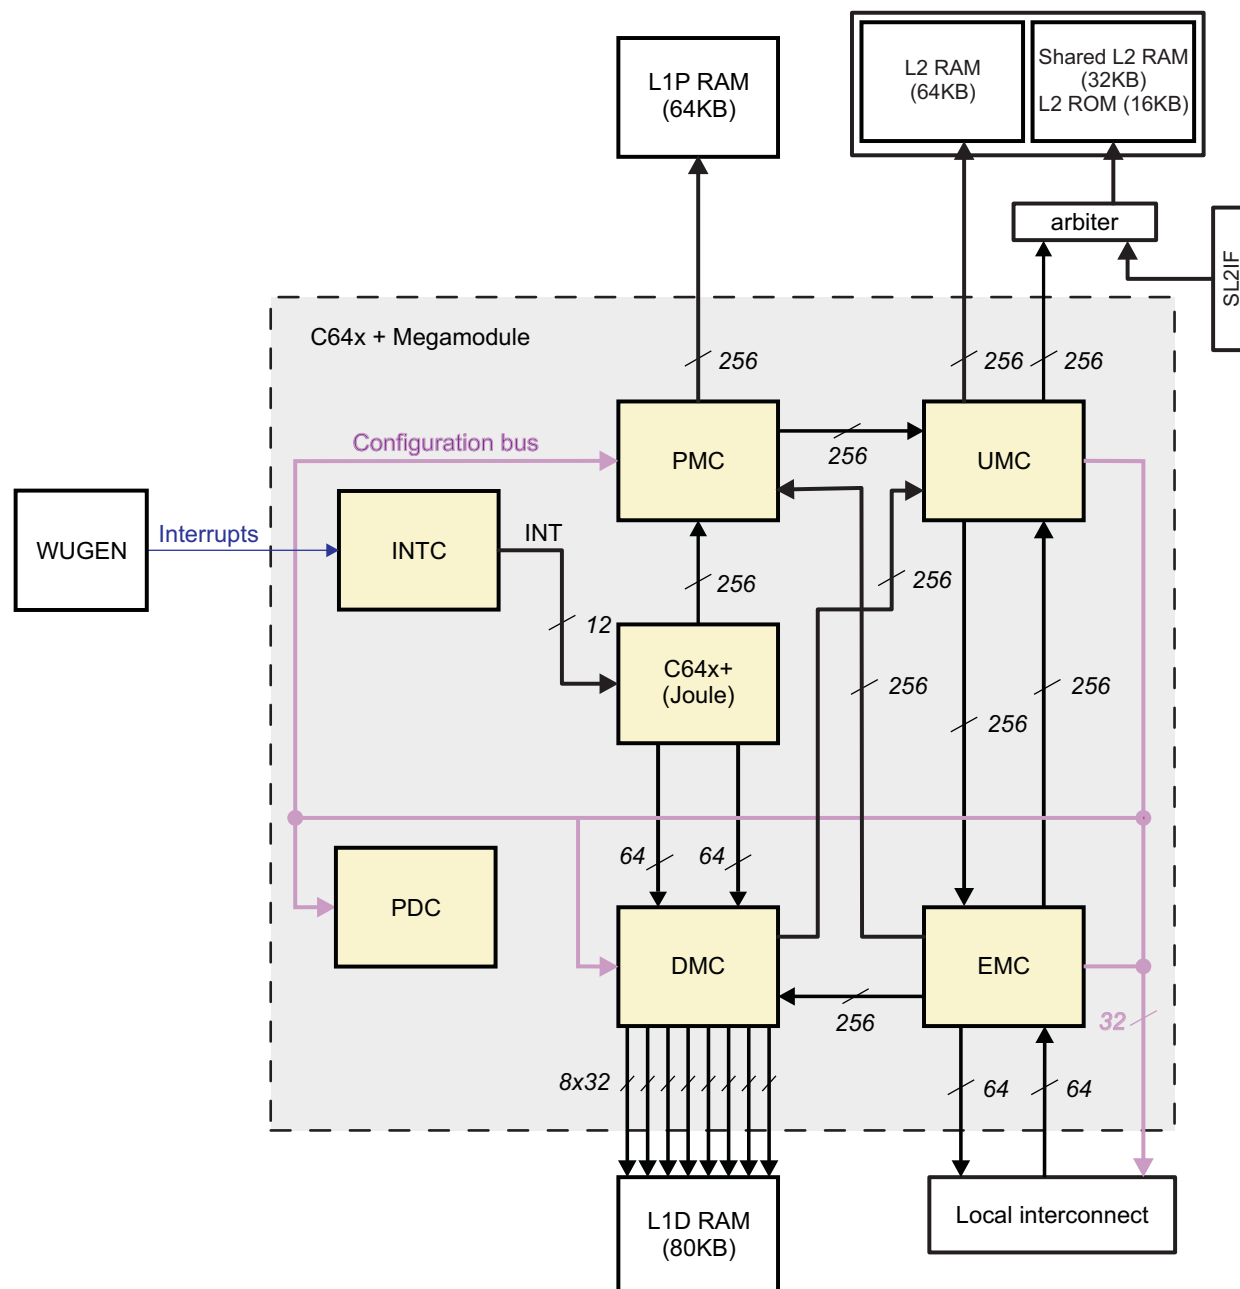

Figure 1-7. IVA2.2 Subsystem Block Diagram

#### 1.3.1 C64x + Megamodule

The C64x + Megamodule is a class of derivative sections of the generalized embedded megacell (GEM). C64x + Megamodule is a hardware-configurable megacell module that comprises a Joule version of the C64x+, an L1 program memory controller (PMC), an L1 data memory controller (DMC), a unified memory controller (UMC), an extended memory controller (EMC), an INTC, and a power-down controller (PDC).

Figure 1-8 is a block diagram of the C64x + Megamodule.

**Figure 1-8. C64x + Megamodule Block Diagram**

### 1.3.1.1 DSP Overview

The C64x+ is an extension of the first C64x DSP section (also named Kelvin).

The C64x features the following:

- 32-bit fixed-point media processor
- VLIW architecture
- 8 instructions/cycle, 8 execution units
  - Optimized instruction set for video and image processing
  - Eight 8 x 8 or 16 x 16 MAC per cycle
  - Eight SAD per cycle

- Eight interpolations  $(a + b + 1) \gg 1$  per cycle
- Two (32-bit x 32-bit > 64-bit) multiply operations per cycle

In addition to existing C64x features, the C64x+ includes the following:

- SPLOOP
- Compact instructions
- Extended function support
- Exception handling
- Privilege mode support
- HLOS time-stamp counter register

C64x+ operates to up to 365 MHz in the context of IVA2.2.

#### **CAUTION**

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

For information about C64x+ DSP, see the Joule reference manual.

### **1.3.1.2 Program Memory Controller Overview**

The PMC is the C64x + Megamodule component that delivers program fetch packets when they are requested by the DSP.

The PMC supports the following features:

- One 256-bit fetch packet per cycle (sustainable)
- 32KB 0-wait state least-significant bit (LSB)-banked SRAM
- L1 program cache controller - 32KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (invalidate)
- Freeze mode support

In the IVA2.2 subsystem, the PMC controls the 32-KB SRAM typically used as cache RAM. However, the allocation of SRAM can be software-configured to keep a section of the memory as memory-mapped SRAM.

For more information, see [Section 1.4.6, Memory Management](#).

### **1.3.1.3 DMC Overview**

The DMC is the C64x + Megamodule component that reads or writes data from/to local memories, as requested by the DSP.

The DMC supports the following features:

- Two 64-bit memory accesses per cycle (sustainable)
- A memory access pair can be any combination of read and write, with no incurred penalty.
- 80KB 0-wait state LSB-banked SRAM
- L1 data cache controller (capabilities listed in [Table 1-8](#)) - 32KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Hardware coherence maintenance with L2 (snooping)

- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass mode support
- Per-page memory-protection attribute check support

The DMC operates to up to 365 MHz in the context of the IVA2.2. The DMC always operates at the same frequency as the DSP.

#### CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

#### 1.3.1.4 UMC Overview

The UMC is the C64x + Megamodule component that reads or writes program and data from/to memory, as requested by the DMC and/or the PMC.

The UMC supports the following features:

- 64KB low-latency state SRAM (first port)
- 32KB low-latency state memory-mapped only SRAM (second port)
- 16KB low-latency ROM (second port)
- L2 unified cache controller (capabilities listed in [Table 1-9](#)) - 64KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM and from ROM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass modes support
- Per-page memory protection attribute check support
- Emulation support
- Long-distance access support (noncacheable data accesses)
- Page-based memory automatic power-down (to clock-off state) and wake-up support

The UMC contains the interfaces to L2 memory, the L1D, the L1P, and the EMC. The EMC houses the interfaces to the EDMA and internal data memory access (IDMA) engines, and thus allows the UMC and ultimately the CPU to communicate with peripherals and external memory.

The UMC has two L2 memory ports, each of which is 256 bits wide. Although accesses to the two ports are initiated serially for each requestor, only one new access is initiated per UMC clock cycle, to avoid memory-bank conflicts between the ports.

The UMC has three requestor ports: the PMC, the DMC, and the EMC. Peripheral configuration and DMA/IDMA interfacing are handled by the EMC. The PMC interface to the UMC consists of a 256-bit read-only path (L1P fetch only). The DMC and the EMC interface to the UMC, and each has separate 256-bit read and write paths of its own.

The UMC operates to up to 182.5 MHz in the context of the IVA2.2. The UMC always operates at half the frequency of the DSP.

#### CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

### 1.3.1.5 EMC Overview

The EMC is the megacell component that reads or writes program and data external memory and configuration registers, as requested by the UMC.

The EMC supports the following features:

- IDMA
- 64-bit slave port for accesses from an external DMA engine and/or host to L1 or L2 memory
- 64-bit master port to serve accesses from the UMC to external memory or configuration registers

The EMC operates to up to 182.5 MHz in the context the of the IVA2.2. The EMC can operate at half or one third the frequency of the DSP.

#### CAUTION

Clock configurations depend on core voltage, please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

### 1.3.1.6 Memory Protection Overview

The C64x + Megamodule memory protection architecture divides the memory map into pages. Each page has an associated set of permissions.

Memory protection provides many benefits to a system:

- Protects operating system data structures from poorly behaving code
- Helps in debugging by providing information about illegal memory accesses
- Prevents unauthorized access to sensitive data (provides device security)
- Allows the OS to enforce clearly defined boundaries between supervisor and user mode accesses, leading to greater system robustness

Memory protection is implemented for the PMC, DMC, UMC, and EMC, and also for the IDMA and EDMA modules.

### 1.3.1.7 INTC

The C64x + Megamodule INTC detects, potentially combines, and routes up to 128 system events (internal and external) to the DSP CPU interrupt lines. [Table 1-5](#) lists the global interrupt mappings of the IVA2.2 subsystem (internal and external interrupts).

The DSP CPU has 12 maskable interrupts and one exception input. The INTC includes an interrupt selector, an exception combiner, and an event combiner. The interrupt selector allows the routing of any of the 128 system events (or a combination of them) to the 12 maskable interrupts of the DSP CPU, and software determines the priorities of those system events. To handle potential conflicts, the 12 CPU interrupts have fixed priorities. The exception combiner allows the combination of any of the 128 system events to the single exception input of the DSP CPU (see [Figure 1-9](#)).

**Figure 1-9. C64x + Megamodule INTC Block Diagram**

iva22-009

**Note:** Not all of the 128 event inputs of the INTC are connected to an internal or external event line. [Table 1-3](#) lists the global interrupt mapping of the DSP INTC. Some interrupts at the IVA2.2 boundary are reserved for future use or are not used by the IVA2.2 subsystem. For information about the DSP core INTC, see the C64x+ DSP documents listed in [Section 1.3.1.8, Other DSP Reference Documents](#).

### 1.3.1.7.1 Event Type

The interrupt controller provides three types of interrupt sources to the DSP CPU:

- Single event
  - A single system event can be directly routed to a CPU interrupt input.
  - A dropped system event is supported through the CPU dropped interrupt reporting mechanism; that is, if the CPU misses the interrupt input, the system event is missed.
- Combined event
  - Up to four event combiners
  - Each combiner allows up to 32 system events to be logically ORed into a single event that can be routed to the DSP CPU.
- Exception event: This event is considered a single event, but it is directly connected to the exception input of the DSP CPU.

### 1.3.1.7.2 Event Behavior

- **Single event source:** The interrupt selector routes 1 of 124 events to a DSP CPU interrupt, as programmed in the interrupt selector registers (IC.INTMUX<sub>i</sub> registers (where *i* is 1 to 3). Logic in the CPU and the INTC combine to detect instances where an interrupt request is asserted before an earlier interrupt request was serviced. The INTC records the interrupt number of the first interrupt and keeps this information until directed to release the interrupt, either through reset or by application software. This record can be used as an additional system event to notify the application of an interrupt failure. Interrupts that qualify for dropped detection are defined through an IDROP mask that sets the IC.INTDMASK register. The masked IDROP event output (EVT96; see [Table 1-3](#)) is available as a system event that can be selected as either a DSP CPU interrupt or an exception event.
- **Combined source:** The event combiners create a combined event from the logical OR of 32 system-event flags qualified by a mask provided through programmable registers (IC.EVTMASK<sub>i</sub> where *i* = 0 to 3). The combination of the event flags creates an event that is asserted when any of the event flags included in its generation is active. Software must clear the event flags (IC.EVTCLR<sub>i</sub> where *i* = 0 to 3) to de-assert a combined event.

---

**Note:** The use of event flags makes it impossible for the CPU to detect the dropping of independent system events; therefore, dropped interrupt capability is not directly supported for combined events.

---

The interrupt event combiners create four shared interrupt sources:

- EVT0: Logical OR of EVTFLAG<sub>i</sub>[31:04] (*i* = 0) masked by EVTMASK<sub>i</sub>[31:04] (*i* = 0)
- EVT1: Logical OR of EVTFLAG<sub>i</sub>[63:32] (*i* = 1) masked by EVTMASK<sub>i</sub>[63:32] (*i* = 1)
- EVT2: Logical OR of EVTFLAG<sub>i</sub>[95:64] (*i* = 2) masked by EVTMASK<sub>i</sub>[95:64] (*i* = 2)
- EVT3: Logical OR of EVTFLAG<sub>i</sub>[127:96] (*i* = 3) masked by EVTMASK<sub>i</sub>[127:96] (*i* = 3)

EVTFLAG<sub>i</sub> are the event flag registers and EVTMASK<sub>i</sub> are the event mask registers. These combined events are presented to the interrupt selection logic.

- **Exception event source:** As with the event combiner, the exception combiner allows multiple system events to be grouped as a single event input to the CPU, and the combiner provides mask registers to remove undesirable events. Because only one exception is input to the CPU, all mask registers work together to combine up to 128 events as a single EXCEP output. This lets the CPU service all available system exceptions.

The shared exception source is created as follows:

EXCEP: Logical OR of EF[127:04] masked by XM[127:04]

Where EF[*i* \* 32 + *j*] = EVTFLAG<sub>i</sub>[*j*] and XM[*i* \* 32 + *j*] = EXPMASK<sub>i</sub>[*j*] (*i* = 0, 1, 2, 3 and *j* = 0 to 31).

The logic is similar to that of the event combiners, except that only one combined event is routed to EXCEP.

### 1.3.1.7.3 Event Detection

The INTC contains a set of status and control registers to manage the status of system events received by the controller. These include set, flag, and clear registers covering all 128 system events. Enabling of the events is managed in the CPU for direct mapped interrupts, in the event combiner for combined events, and in the exception combiner for system exceptions. Events to the interrupt controller can be enabled/disabled only at the event source.

The event flag registers (IC.EVTFLAG<sub>i</sub> where *i* = 0 to 3) capture every system event received, regardless of its destination: event combiner, exception combiner, or interrupt selector. Events that are not masked by either the event combiner or the exception combiner are captured in the IC.EVTFLAG<sub>i</sub> (where *i* = 0 to 3) register corresponding to the event, and are used to determine when the combined event is generated. Events that are masked by either the event combiner or the exception combiner are captured in the IC.EVTFLAG<sub>i</sub> register, but do not affect when the DSP CPU interrupt is generated.

The event flags in the IC.EVTFLAG<sub>i</sub> registers retain the value of 1 for any event received. These registers are read-only and must be cleared through the write-only IC.EVTCLR<sub>i</sub> registers. The IC.EVTSET<sub>i</sub> registers can be used to manually set bits in the IC.EVTFLAG<sub>i</sub> registers, including those that are masked.

**Note:** Because external events are maintained by the peripheral until they are explicitly cleared by software, drop event detection does not work for external events (interrupts from peripherals external to the IVA2.2 subsystem).

#### 1.3.1.7.4 Event Selection

The DSP CPU has 12 available maskable interrupts. The interrupt selector allows any of the 128 system events, either from the event inputs or from the event combiners, to be routed to any of the 12 CPU interrupt inputs (see [Figure 1-10](#)).

**Figure 1-10. Interrupt Selector Block Diagram**

iva22-010

The user can choose which of the 128 input events is mapped to each of the 12 CPU interrupts by writing the event number in the bit field corresponding to the CPU interrupt in the INTMUXi register. CPU priority is fixed. This event -> interrupt mapping allows software to define the priority of the event. For more information, see [Section 1.4](#), *IVA2.2 Subsystem Basic Programming Model*.

#### 1.3.1.7.5 Event Combination

The event combiner allows multiple system events to be combined as single event for routing to the interrupt selector. This allows the CPU to service all available system events, even though only 12 are available.

A set of event mask registers (IC.EVTMASKi where i = 0 to 3), is used to program the event combiner. These registers allow up to 32 events to be combined as a single event output that is used as a single DSP CPU interrupt. The event mask bits in the EVTMASKi registers act as enablers for the received system events combined on the event outputs. There are four event outputs to the interrupt selector (EVT[3:0]).

By default, every system event is unmasked and combined with its associated EVTx. To mask out an event source (for example, to disable an event from being combined), the corresponding mask bit (the IC.EVTMASKi[y] EMy bit for EVTy) must be set to 1.

---

**Note:** Because the event masks for events 0 through 3 are combined events and thus cannot contribute to the generation of a combined event, they are reserved.

---

For more information, see [Section 1.4.5, Interrupt Management](#).

#### 1.3.1.7.6 Interrupt Event Error

The INTC can generate a system event internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is received while the interrupt flag (IFR, internal DSP register) is already set in the CPU. This signals possible problems in the code, such as whether interrupts were disabled for an extended time, or whether pipelined (noninterruptible) code sections were too long.

---

**Note:** The same strategy of register settings (events, event set, event clear, event mask) is used in the WUGEN (which is not really an INTC), which enables defining wake-up events so that they can wake up the IVA2.2 subsystem. For more information, see [Section 1.3.4, Wake-Up Generator](#).

---

For more information, see [Section 1.4.5, Interrupt Management](#). See [Section 1.4, IVA2.2 Subsystem Basic Programming Model](#), for information on associated programming.

#### 1.3.1.7.7 PDC Overview

The C64x + Megamodule PDC allows power management under software control. Different power-down states are defined and can be reached during a period of DSP inactivity. The PDC ensures handshakes with C64x + Megamodule modules so that they go to power-down state in the correct order, on request from the user, and publishes the relevant standby status to the IVA2.2 SYSC module.

The power-down attributes of the C64x + Megamodule components are mapped through the PDC, through the SYS.PDCCMD register.

For information about power-down settings, see [Section 1.4.7.3, Power-Down and Wake-Up Management](#).

#### 1.3.1.8 Other DSP Reference Documents

For more information about the C64x + Megamodule architecture, the instruction set, and the DSP core interrupt controller, and for a complete description of the DSP memory-mapped registers, see the following documents:

- *TMS320C64x+ DSP Megamodule Reference Guide* (TI literature number SPRU871C) describes the C64x+ megamodule peripherals.
- *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* (TI literature number SPRU732)
- *High-Speed DSP Systems Design Reference Guide* (TI literature number SPRU889) provides recommendations for meeting the many challenges of high-speed DSP system design. These recommendations include information about DSP audio, video, and communications systems for the C5000 and C6000 DSP platforms.

## 1.3.2 DMA Engines

### 1.3.2.1 EDMA

The IVA2.2 subsystem has an EDMA to transfer instructions and data from/to any external memory connected to the L3 interconnect to/from the C64x + Megamodule L1D and L2 and, potentially, L1P (if not configured as full cache) local memories. The EDMA can also perform transfers from external memory to external memory and from C64x + Megamodule internal memory to C64x + Megamodule internal memory, with some performance loss caused by resource sharing between the read and write ports. For C64x + Megamodule internal memory to internal memory, use the IDMA.

For the IDMA functional description and a description of IDMA relative programming, see [Section 1.3.2.3, IDMA](#), and [Section 1.4.3.2, Internal Memory-to-Memory Transfer \(IDMA\)](#), respectively.

The EDMA is based on two primary components:

- Third-party DMA channel controller (TPCC)
- Third-party DMA transfer controller (TPTC)

There are two instances of the TPTC in the IVA2.2 subsystem.

[Figure 1-11](#) shows how the EDMA is integrated in the IVA2.2 subsystem:

- Code running on the DSP can configure the EDMA; through the C64x + Megamodule configuration port and the local interconnect, the code can program DMA transfers and software-trigger them by writing to the TPCC configuration registers.
- Preprogrammed DMA transfers can be triggered by external events, referred to in this chapter as DMA requests.
- The TPCC schedules DMA transfers to the TPTC DMA engines (TPTC0 and TPTC1) through dedicated local interconnect 32-bit configuration ports.
- Each TPTC issues concurrent traffic on the local interconnect through dedicated read and write 64-bit ports.
- Interrupts generated by the EDMA are routed to the DSP INTC.
- Power-management handshakes are exchanged between EDMA components and the SYSC module.

Figure 1-11. IVA2.2 EDMA Overview

### 1.3.2.1.1 Third-Party Channel Controller

The TPCC is the DMA transfer scheduler responsible for scheduling, arbitrating, and issuing user-programmed transfers to the two TPTCs.

#### 1.3.2.1.1.1 TPCC Features

The TPCC features are as follows:

- Parameter RAM (PaRAM entries) holding up to 128 transfer contexts, with the following capabilities:
  - Ping-pong and circular buffering
  - Channel chaining
  - Auto-reloading

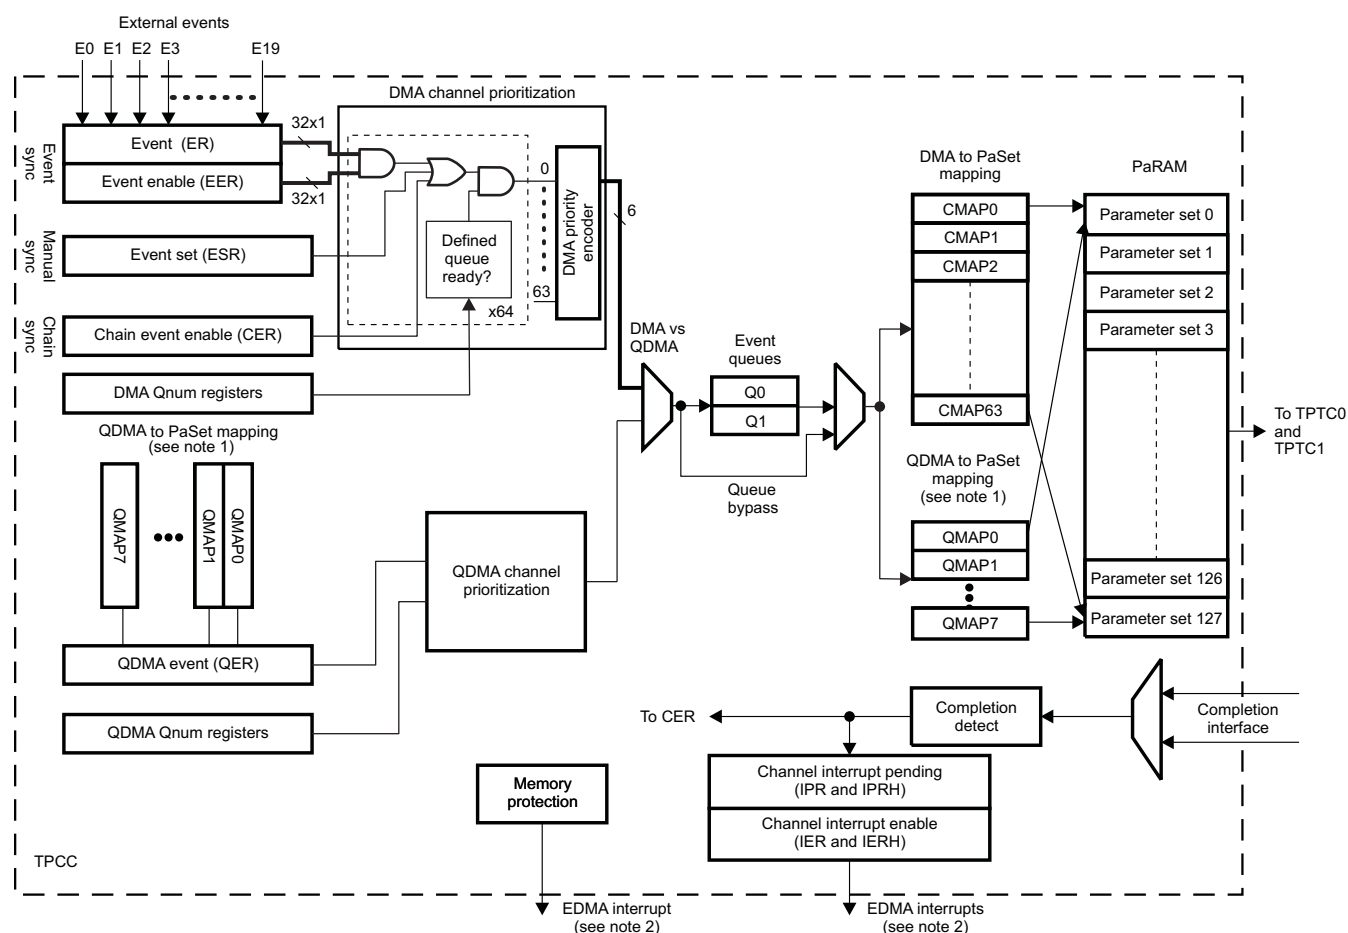

Each PaRAM entry can be used as a DMA entry (up to 64), QDMA entry (up to 8), or link entry (remaining):

- Up to 64 DMA logical channels:

- 64 channels can be triggered explicitly by the DSP CPU (DMA entry).
- 64 channels can be triggered by 20 external events (see [Table 1-2](#)).
- All channels can be triggered by completion of a previous transfer in a user-programmed chain of transfers (linked entry).
- 8 channels can be triggered automatically and indirectly by the CPU using the IDMA, reducing CPU offload for DMA configuration (QDMA entry).
- 12 interrupt lines connected to the DSP CPU
- Boundaries for synchronization with the CPU are programmable.
- Two queues holding events waiting for submission to TPTC
- Memory protection
- Each transfer can be programmed to a priority level (three possible levels).

Figure 1-12 is a block diagram of the TPCC.

**Figure 1-12. TPCC Block Diagram**

iva22-012

#### Notes:

1. Although it is depicted twice in [Figure 1-12](#), there is only one physical register set for the QDMA to PaRAM set mapping block.
2. For more information, see [Table 1-3](#).

A channel is a specific event that can cause a transfer to be submitted to the TPTCs as a transfer request. The TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for the ways they are triggered:

- DMA channels can be triggered by external events (such as McBSP TX Evt and McBSP RX Evt) by the software writing 1 to a given bit location or channel, by the event set register, or through chaining.
- QDMA channels are triggered automatically (auto-triggered) by the CPU using the IDMA. QDMAs allow a minimum number of linear writes (optimized for the C64x + Megamodule IDMA feature) to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among all pending DMA/QDMA events with a fixed 64:1 and 4:1 priority encoder for DMA and QDMA events, respectively (a low channel number corresponds to a high priority). DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controller, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority, Q0 higher than Q1. When an event is ready to be queued and both the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the TR bus/PaRAM processing is busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the TPTC is available for a new TR to be programmed into the TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry. The PaRAM entry consists of eight words of DMA context, including source address, destination address, count, indexes, etc.

#### 1.3.2.1.1.2 DMA Versus QDMA

The only difference between a QDMA and a DMA transfer is the specific means of generating/recognizing TR synchronization. From the user point of view, DMA and QDMA transfer types can be combined to perform various types of transfers.

DMA channel TR synchronization can be generated from one of three sources:

- Event-triggered: The event register (TPCC\_ER) channel *n* bit is set as the result of an external event. An external event is latched in the event register. If the corresponding event is enabled through the event enable register (TPCC\_EER), this is recognized as a TR synchronization.
- Manually triggered: The event set register channel *n* bit is set manually to the event set register (TPCC\_ESR and TPCC\_ESRH registers) for channel *n* (TPCC\_ESR[*n*] *En* bit or TPCC\_ESRH[*n*] *En* bit). Manually set events do not need to be enabled to be recognized as a TR synchronization.
- Chain-triggered: The chain event register channel *n* (TPCC\_CER and TPCC\_CERH registers) bit is set when a chaining completion code is detected on the completion interface for channel *n*. Chain events do not need to be enabled. If a chain trigger is detected, this is always recognized as a TR synchronization.

QDMA TR synchronization occurs one of two ways:

- Auto-triggered: The QDMA event register channel *n* (TPCC\_QER and TPCC\_QERH[*n*] *En*) bit is set when a CPU write address matches the address defined by the QDMA mapping register for channel *n* (TPCC\_QCHMAPj) and the QDMA channel is enabled (TPCC\_QEER[*n*] *En* bit field).
- Link-triggered: The TPCC\_QER[*n*] *En* bit is set when a link update is performed on a PaRAM address that matches the TPCC\_QCHMAPj setting, and the TPCC\_QEER[*n*] *En* bit is set.

There is a subtle difference between each trigger type and the associated enablers. Event assertion always results in the TPCC\_ER[*n*] *En* bit being set, regardless of the state of the enable (TPCC\_EER.*En*). It is recognized as a TR synchronization only if enabled. Chain triggering always sets the TPCC\_CER[*n*] *En* bit and is always treated as a TR synchronization. Manual triggering always sets the TPCC\_ESR[*n*] *En* bit and is always treated as a TR synchronization. Auto-triggering (QDMA) sets only the event register TPCC\_QER[*n*] *En* bit only if the corresponding event is enabled (TPCC\_QEER[*n*] *En*); when the TPCC\_QER[*n*] *En* bit is set, it is always treated as a TR synchronization.

For more information, see [Section 1.4](#), IVA2.2 Subsystem Basic Programming Model.

### 1.3.2.1.1.3 DMA/QDMA Channel Mapping and PaRAM Entry

The DMA and QDMA channel mapping registers (TPCC\_DCHMAPi and TPCC\_QCHMAPj) allow each DMA and QDMA channel to be mapped to arbitrary locations in the PaRAM memory map. The entry is designated with a 9-bit PAENTRY (TPCC\_DCHMAPi[13:5] PAENTRY and TPCC\_QCHMAPj[13:5] PAENTRY bit fields) PaRAM entry number that defines the entry number in a 128-entry maximum PaRAM (see [Figure 1-13](#)). TPCC\_QCHMAPj[4:2] TRWORD points to the trigger word of the PaRAM entry defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.

**Figure 1-13. DMA/QDMA Channel Mapping and PaRAM Entry**

iva22-013

**Note:** Each parameter entry of PaRAM is organized as eight 32-bit words or 32 bytes, as shown in [Figure 1-13](#).

The location of fields in each entry, as well as bit positions in the options field, must match the TR packet format as closely as possible to the requirements of the TPTC0 and TPTC1 programming. Each PaRAM entry consists of 16-bit and 32-bit parameters that correspond to the transfer geometry. For more information about the parameters, see [Section 1.3.2.1.1.2, DMA Versus QDMA](#).

#### 1.3.2.1.1.4 Types of TPCC Transfers

The TPCC streamlines transfers into an orthogonal transfer structure that is always defined by three dimensions. Of the three dimensions, only two synchronization types are supported: 1D synchronized transfers and 2D synchronized transfers; 3D synchronized transfers can be logically achieved by chaining.

The following terms are used:

- 1-dimension (1D) transfer or array: ACNT contiguous bytes transfer. For information about the 1D transfer programming model, see [Section 1.3.2.1.1.5, Transfer Synchronization](#).
- 2-dimension (2D) transfer or frame: BCNT arrays of ACNT bytes transfer. Each array transfer in 2D transfer is separated from the other transfers by an index programmed through the TPCC.SBIDX or TPCC.DBIDX registers.
- 3-dimension (3D) or block: CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the third dimension is separated from the previous transfer by an index programmed by the TPCC.SCIDX or TPCC.DCIDX registers. The reference point for the index depends on the synchronization type.

#### 1.3.2.1.1.5 Transfer Synchronization

In a 1D synchronized transfer, each TPCC TR synchronization triggers the transfer of the first dimension of ACNT bytes, or one array of ACNT bytes. In other words, each TR packet consists of transfer information for only one array. Arrays can be separated by SBIDX and DBIDX, as shown in [Figure 1-13](#), where the start address of array N equals the start address of array 1 plus SRC or DST BIDX. Frames can be separated by SCIDX and DCIDX. For 1D synchronized transfers, after the frame is exhausted, the address is updated by adding (S|D)CIDX to the beginning address of the last array in the frame.

Contrast this to the (S|D)CIDX update in 2D synchronized transfers, which are referenced from the beginning address of the first array in the previous frame. For information about parameter updates, see [Section 1.3.8, Error Reporting](#).

In a 2D synchronized transfer, each TR synchronization triggers the transfer of two dimensions or one frame. In other words, each TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Arrays can be separated by SBIDX and DBIDX, as shown in [Figure 1-15](#). Frames can be separated by SCIDX and DCIDX. For 2D synchronized transfers, after a TR for the frame is submitted, the address is updated by adding (S|D)CIDX to the beginning address of the beginning array in the frame. Contrast this to the (S|D)BIDX update in 1D synchronized transfers. For information about parameter updates, see [Section 1.3.8, Error Reporting](#).

#### 1.3.2.1.1.6 DMA Channel Prioritization

If multiple trigger sources (event trigger/chain trigger/manual trigger) for a single channel are active at the same time, the TPCC services events in the following order:

1. Event trigger (through event register [ER])
2. Chain trigger (through chain event register [CER])
3. Manual trigger (through event set register [ESR])

#### 1.3.2.1.1.7 Transfer Completion

Transfer completion can be used for two different mechanisms in the TPCC:

- Generating chained events
- Generating interrupts to an external processor

The underlying mechanism for both features is the same. The user programs the PaRAM Options field with a specific transfer completion code (TPCC\_OPTm[17:12] TCC) and indicates whether that completion code is to be used to generate a chained event and/or to generate an interrupt on completion of a transfer (either or both can be done). The user can selectively program whether completion signaling is enabled for the final TR of a PaRAM set, for all except the final TR of a PaRAM set, or for all TRs of a PaRAM set. The specific TCC value (6-bit binary value) programmed by the user dictates which bit of the 64-bit CER and/or interrupt pending register (IPR) is used.

There is no direct correlation between the TCC value used for a specific PaRAM entry and the channel number for that entry. Software controls the allocation of TCC values. There is always a 1:1 relationship between the TCC value and the IPR bit and/or the CER bit set when that transfer completes. For example, completion of the PaRAM entry for channel 0 can chain-trigger the PaRAM entry for channel 1.

### 1.3.2.1.2 Third-Party Transfer Controller

The TPTC is the DMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

---

**Note:** The port data bus width of the instances of the TPTC is fixed at 64 bits.

---

#### 1.3.2.1.2.1 TPTC Features

The TPTC features are as follows:

- Pipelined transfers (multiple in-flight transfers)
- Background programming
- 2D or 1D transfer
- Increment addressing modes
- Clock-stop handshaking with the SYSC controller
- Programmable tracking of transfer completion
- 2D qualifications of transfers to allow 2D bandwidth optimization

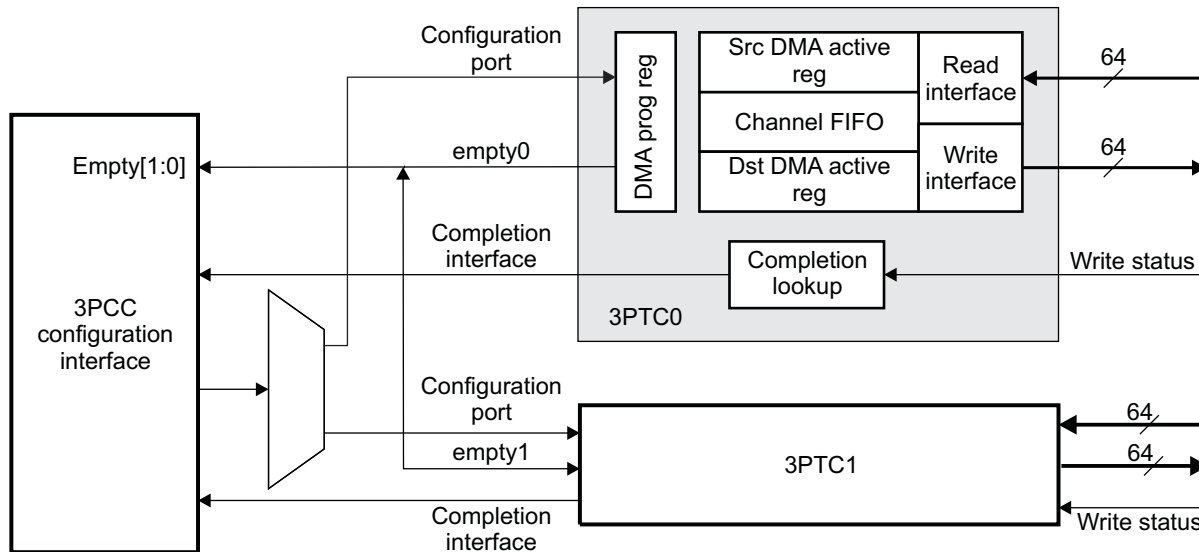

Two instances of the TPTC generate concurrent traffic on the IVA2.2 local interconnect. Each TC controller consists of the following components:

- **DMA program register set:** Stores the context for the DMA transfer that is loaded into the active register set on completion of the current active register set. The CPU or TPCC programs the program register set, not the active register set. For typical stand-alone operation, the CPU programs the program register while the TC services the active register set. The program register set includes ownership control that synchronizes the CPU software and the DMA.
- **Source DMA active register set:** Stores the context (src/dst/cnt/etc) for the DMA transfer request in progress in the read controller. The active register set is split into independent source and distant register halves, because the source local interconnect controller and distant local interconnect controller operate independently of each other.
- **Distant DMA register set:** Stores the context (src/dst/cnt/etc) for the DMA transfer request in progress, or pending, in the write controller. The pending register sets are required to allow the source controller to begin processing a new TR while the distant register set is still processing the previous TR.
- **Channel FIFO:** Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the data FIFO and then written to the destination peripheral by the write command/data bus.
- **Read controller/local interconnect read interface:** The local interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 64 bytes and the available landing space in the channel FIFO.
- **Write controller/local interconnect write interface:** The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 64 bytes and available data in the channel FIFO.
- **Completion interface:** The completion interface sends completion information to the TPCC for posting interrupts in the TPCC.
- **Configuration port:** Slave interface that provides read/write access to program registers, and provides read access to all memory-mapped TC registers. For information about TPTC registers, see [Section 1.5, IVA2.2 Subsystem Registers](#).

[Table 1-4](#) lists the hardware settings.

[Figure 1-14](#) shows the internal structure of the TPTC and its connection to the TPCC.

Figure 1-14. TPTC Block Diagram

The primary responsibility of the TPTC is to perform read and write transfers through the local interconnect to the slave peripherals, as programmed in the active and program register sets:

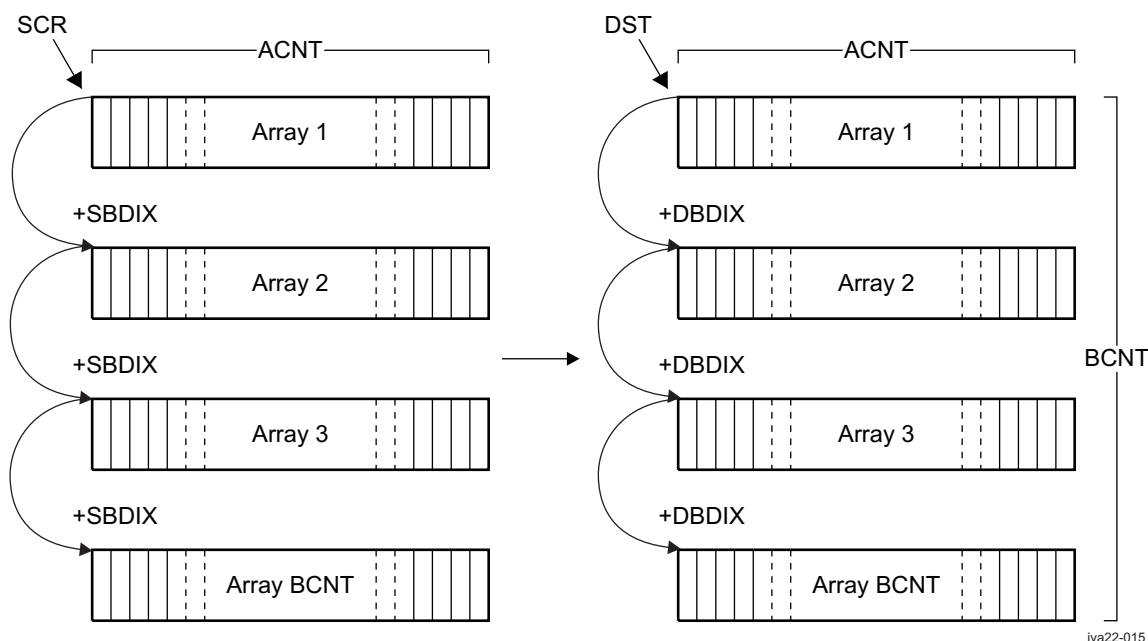

- In the TC stand-alone use model, the user directly programs the program and active register sets for a given channel (TPTC0 or TPTC1). Because of the TPCC, this mode is not the use case targeted for device applications, so it is not emphasized in this chapter. For information about its programming model, see [Section 1.4.3.6.6, Direct Configuration to Transfer Channel \(Not Recommended\)](#).
- In the TC external-control use model, the user does not directly program the active and program register sets. Instead, the TPCC is the user interface to the EDMA system, and the TPTCs (TPTC0 and TPTC1) are slaves to the TPCC. This is the use case of the EDMA in device applications.

#### 1.3.2.1.2.2 Transfer Geometry

The TPTC supports a transfer geometry fully defined by the registers summarized here (see [Figure 1-15](#)).

- OPTx = options, (where x = 0, 1)
  - SAM = Source address mode, controls whether the source array is from incrementing addresses or from a single FIFO address
  - DAM = Distant address mode, controls whether the destination array is to an incrementing address or to a single FIFO address
  - FWID = Controls the width of the FIFO
- SRC = Source address
- DST = Distant address
- CNT = BCNT, ACNT
  - ACNT = Number of bytes in each array
  - BCNT = Number of arrays in each TR
- BIDX = DBIDX, SBIDX
  - SBIDX = Source B-dimension index, defines the address offset between starting addresses of each source array
  - DBIDX = Distant B-dimension index, defines the address offset between starting addresses of each destination array

**Figure 1-15. Transfer Geometry**

**Note:** Many Texas Instruments DMA controllers employ a concept of element size and element indexing. To maintain orthogonality, the concept of element size has been dropped. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that must be transferred.

### 1.3.2.1.2.3 Tracking Transfers

Each TPTC channel consists of three register sets: a program register set, a source-active register set, and a distant FIFO register set. The status of each of these register sets is indicated by the PROGBUSY, SRCACTV, DSTACTV, and WSACTV status bits, which are user-readable in the TPTCj\_TCSTAT register.

The program register set (TPTCj\_POPT, TPTCj\_PSRC, TPTCj\_PCNT, TPTCj\_PDST, TPTCj\_PBIDX, and TPTCj\_PMPPRXY) is never modified by the TPTC, because they are simply holding registers processed by the active register sets. The source active register set (TPTCj\_SAOPT, TPTCj\_SASRC, TPTCj\_SACNT, TPTCj\_SADST, TPTCj\_SABIDX, TPTCj\_SAMPPRXY, TPTCj\_SACNTRLD, TPTCj\_SASRCBREF, and TPTCj\_SADSTBREF) tracks commands for the source side of the transfer, and the distant FIFO register set (TPTCj\_DFOPTi, TPTCj\_DFSRCi, TPTCj\_DFCNTi, TPTCj\_DFDSTi, TPTCj\_DFBIDXi, and TPTCj\_DFMPPRXYi) tracks commands for the distant side of the transfer.

As the source and distant controllers process a TR, the SRC, DST, and CNT fields must be continuously updated as commands are issued. A reference value for these registers is also maintained. The active register set uses the reference address (SRCBREF and/or DSTBREF) to calculate the addresses of the subsequent arrays in a transfer. This is required because subsequent arrays are defined as an offset from the starting address of the current array. Similarly, when a new array begins, the CNT must be restored (from CNTRLD) to the originally programmed value and decremented as the new array is processed.

The following summarizes register use for the active register sets:

- Static fields
  - OPT
  - BIDX = DBIDX/SBIDX
- Dynamic fields
  - SRC = Source address of the next read command to be issued
    - Tracked by source active register set
  - DST = Distant address of the next write command to be issued

- Tracked by distant FIFO register set
  - CNT = BCNT/ACNT
    - BCNT = Number of arrays remaining to be transferred. This includes the current array; that is, BCNT is decremented after all commands for an array are issued (or at least after all read or write commands are scheduled).
    - ACNT = Number of bytes remaining to be transferred
    - Tracked independently in source and distant FIFO register sets
  - Reference fields
    - CNTRLD = ACNTRLD only
      - CNTRLD.ACNTRLD is set with the initial CNT.ACNT value. The reload value is copied into CNT.ACNT when CNT.ACNT decrements to 0.
      - Tracked independently in source and distant FIFO register sets
- Because a command is complete when BCNT decrements to 0, there is no BCNT reload value.
- SRCBREF = Source address reference points to the starting address of the array being read. The starting address of the next array is calculated as SRCBREF + SBIDX.
    - Tracked by source active register set
  - DSTBREF = Distant address reference points to the starting address of the array being written. The starting address of the next array is calculated as DSTBREF + DBIDX.
    - Tracked by distant FIFO register set

#### 1.3.2.1.2.4 Completion Interface to TPCC

The TPCC can request that the TPTC send completion information to the TPCC when a TR completes. Completion status is requested in the TR options registers (TPTCj\_DFOPTi[20] TCINTEN and TPTCj\_DFOPTi[22] TCCHEN bits, and TPTCj\_DFOPTi[17:12] TCC where i = 0 to 3 when j = 0 and i = 0 or 1 when j = 1).

If TCINTEN or TCCHEN is set to 1, the TPTC must return completion information on completion of the entire TR. The TPCC uses completion information for chaining (enabled by TCCHEN) or for posting interrupts (enabled by TCINTEN).

The TPTC generates status conditions based on completion of a transfer (TPTCj\_INTSTAT[1] TRDONE bit) and based on the program register set transitioning to the downstream registers (TPTCj\_INTSTAT[0] PROGEMPTY bit).

These two conditions can be enabled by the corresponding bits in the TPTCj\_INTEN register to generate an interrupt to the DSP CPU through the TCERRINTx interrupt line (TCERRINT0 for TPTC0 and TCERRINT1 for TPTC1). For the event mapping of these interrupt lines, see [Table 1-2](#).

---

**Note:** Status bits TRDONE and PROGEMPTY are always available and are stored in the TPTCj\_INTSTAT register regardless of use model and regardless of whether the corresponding bits are enabled. Typically, these bits are not used in the TPCC use model. They are used in a stand-alone use model in which the user directly programs the TC.

---

For more information about EDMA completion and its programming model, see [Section 1.4.3.1, Transfers From/to Device Memories/Peripherals \(EDMA\)](#).

#### 1.3.2.1.3 EDMA Hardware Parameters

[Table 1-4](#) lists the hardware parameter settings for the IVA2.2 subsystem.

**Table 1-4. IVA2.2 EDMA Hardware Parameters**

Module		Parameter	IVA2.2
EDMA	TC	FIFO size for TC0	256 bytes
		FIFO size for TC1	128 bytes
		Data bus width	64 bits
		TR pipelining depth TC0	4
		TR pipelining depth TC1	2
		Endianness	Little
		Burst size	64
	CC	Number of DMA channels	64
		Number of QDMA channels	8
		Number of PaRAM entries	128
		Number of Event Qs	2
		Number of TPTCs	2

**Note:** The TR pipelining depth controls the number of read TRs for a given transfer channel that can be serviced by the source transfer controller without being serviced by the distant transfer controller. This dictates the amount of storage required in the distant queue channel registers for in-flight TRs

The user cannot directly program burst size, as with the sDMA, but must rely on the ACNT/BCNT and issue 1D synchronization transfers to do so.

### 1.3.2.2 EDMA Access to Video Hardware Accelerator

To improve performance and to offload themselves, the C64x + Megamodule and sequencer can both program the EDMA in IVA2.2 to transfer memory to/from the video accelerator to/from external memories. The C64x + Megamodule programs the EDMA through the IVA2.2 local interconnect.

The DMA accesses the video hardware accelerator with the memory mappings listed in [Table 1-5](#).

**Table 1-5. EDMA Memory Mapping for the Video Hardware Accelerator**

Device Name	Start Address (Hex)	End Address (Hex)	Size (in Kbytes)
Video Hardware Accelerator Registers	0x0000 0000	0x000F 7FFF	992
Video interconnect CFG	0x000F 8000	0x000F BFFF	16
Reserved	0x000F C000	0x000F FFFF	16
Other MEMS and PERIPHS	0x0010 0000	0xFFFF FFFF	4,193,280

### 1.3.2.3 IDMA

The IDMA is a simple DMA engine that performs block transfers between any two memory locations local to the C64x + Megamodule. A local memory has a controller that is included in the C64x + Megamodule. Local memory can be L1P, L1D, or L2 memories or C64x + Megamodule port configuration for an offloaded configuration. The IDMA controller consists of two DMA channels (channel 0 and channel 1) that can be independently programmed (a dedicated set of registers) to perform block moves between internal C64x + Megamodule resources.

IDMA channel 0 is used only to configure registers of IVA2.2 modules connected to the C64x + Megamodule configuration port, and it is useful for the DMA PaRAM entries.

To allow an easy configuration of IVA2.2 modules, the IDMA channel contains five registers: status, mask, source address, destination address, and window count.

For information about the use of channel 0 for an offloaded configuration, see [Section 1.4.3.6.5, Offloaded Configuration \(Using IDMA\)](#).

IDMA channel 1 allows transfers between any two C64x + Megamodule local internal memories (L2, L1P, L1D). Channel 1 is intended for background transfers in internal memory, such as block moves between the relatively high-latency L2 and the zero-latency L1D SRAM. This lets the CPU process data directly within L1D with minimal CPU impact.

For more information, see [Section 1.4.3.2, Internal Memory-to-Memory Transfer \(IDMA\)](#).

### 1.3.3 MMU

The IVA2.2 MMU communicates accesses from the DSP core of the IVA2.2 subsystem to the L3 interconnect, mapping the 4G bytes of the DSP virtual addresses to any place in the 4G-byte address space of the device.

At reset, the MMU is disabled, and the IVA2.2 DSP CPU can access device global memory mapping from the 0x1100 0000 address. The range of addresses 0x00000000 to 0x10FF FFFF is reachable only by the DSP CPU, because it performs its own internal memory-mapping function. For more information, see the *Memory Mapping* chapter.

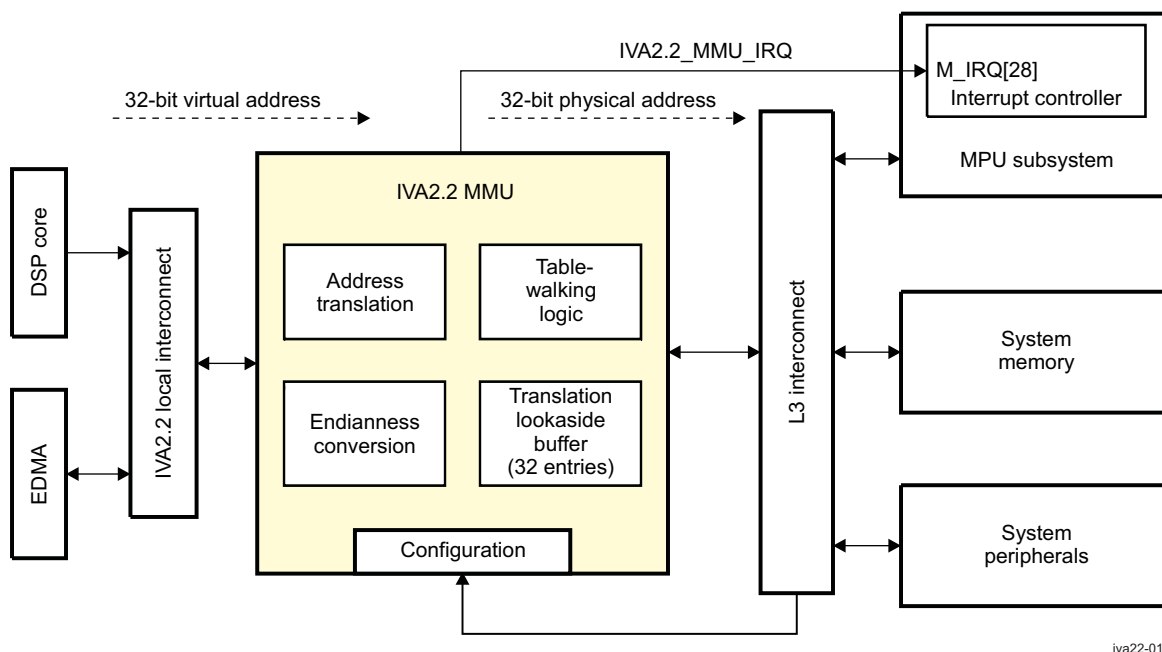

The IVA2.2 MMU main features are:

- 32 entries/fully associative translation look-aside buffer (TLB)
- One interrupt line to the MPU
- 32-bit virtual addresses, 32-bit physical addresses
- 4-KB and 64-KB pages, 1-MB section, 16-MB super-section
- Predefined (static), software-driven (interrupt-based) or table-driven (hardware table-walker) software translation strategies

**Note:** The endianness conversion capability of the MMU module is not used in the IVA2.2 subsystem (the DSP is configured as a little-endian processor in the device). With this configuration, the MMU2.MMU\_RAM[9] ENDIANNESS bit setting is ignored, even if the user changes the value.

Figure 1-16 shows the integration and functionality of the IVA2.2 MMU module.

Figure 1-16. IVA2.2 MMU Block Diagram

iva22-016

### 1.3.3.1 MMU VA-to-PA Translation

The IVA2.2 MMU translates the 32-bit DSP external addresses to physical addresses in the 32-bit MPU address space. Address translation is performed by a translation table structure (TTB) that maps the most-significant bits (MSBs) of the DSP byte address to another set of MSBs of a 32-bit MPU byte address. The least-significant bits (LSBs) of the DSP-generated byte address are used as page/section indices in the address translations and are not altered when forming the new 32-bit physical address. The TTB translations are expedited by a TLB that serves as a cache of recently used page translations. The address mapping can be programmed at the TTB level or by writing the TLB entries directly. The IVA2.2 MMU contains 32 TLB entries that can be configured to remap 4-KB, 64-KB, 1-MB, or 16-MB segments of memory.

The TLB can be managed statically or dynamically (through the use of interrupts) by the MPU OS, but the MMU also includes hardware table-walking logic that lets the MMU autonomously traverse the page table on a TLB miss. On a TLB miss, the translation table-walking logic automatically retrieves the information from the translation table stored in physical memory and updates the TLB cache.

Figure 1-17 shows the TTB structure in detail.

**Figure 1-17. IVA2.2 MMU Translation Table Hierarchy**

iva22-017

**Note:** The MMU passes the lower bits of the virtual address unchanged.

### 1.3.3.2 MMU Configuration

If the IVA2.2 MMU requires software intervention, the MPU services the event; IVA2.2 MMU service requests are signaled to the MPU with a dedicated interrupt, M\_IRQ[28].

Generally, the MMU is initialized at boot time, but it can also be dynamically reprogrammed. Typically, the MMU is programmed by the MPU through the IVA2.2 slave port on the L3 interconnect when a new task is created on the IVA2.2 subsystem. But the DSP also has access to the MMU configuration registers for the save and restore process. At reset, MMU is disabled and DSP virtual addresses are passed directly through as physical addresses (not translated). IVA2.2 MMU configuration registers are at system base address 0x5D00 0000.

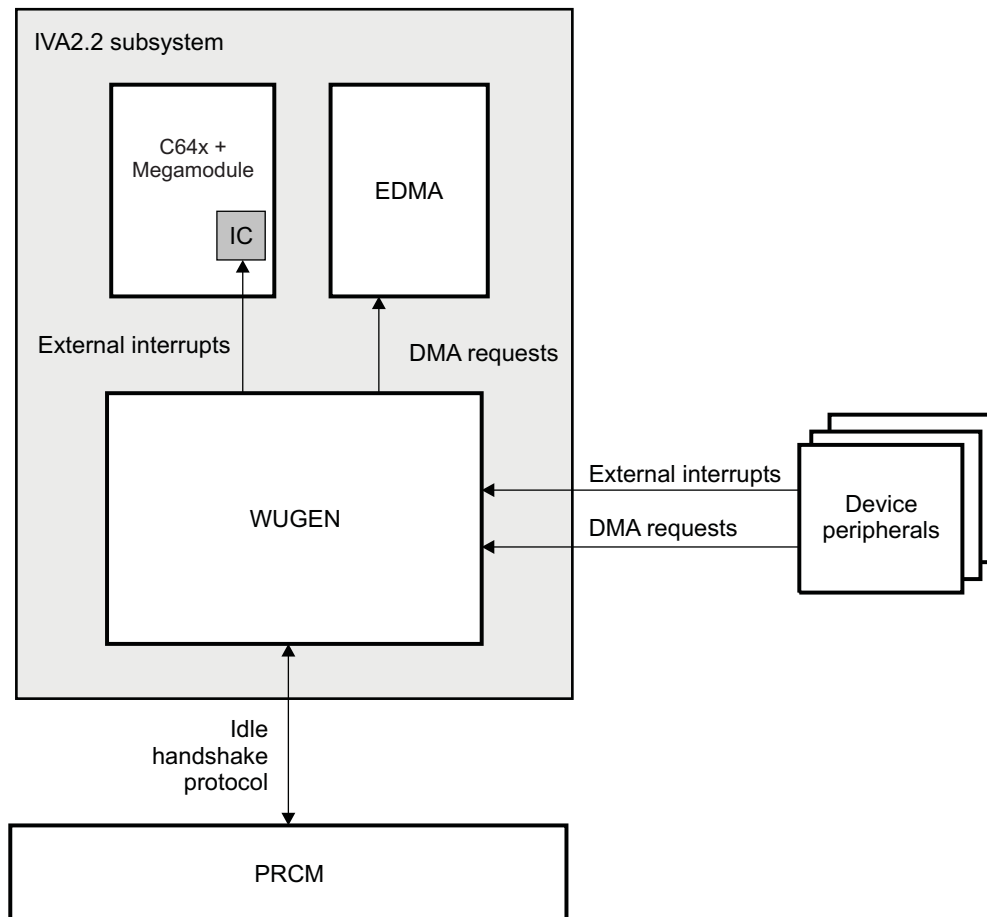

For more information about the functionality of the IVA2.2 subsystem MMU module, including interrupts, register descriptions, and programming model, see the *Memory Management Units* chapter.

### 1.3.4 Wake-Up Generator

The wake-up generator (WUGEN) controls the following:

- Implementing the IVA2.2 idle handshake protocol with the PRCM
- Resynchronizing interrupts and DMA requests from device peripherals external to the IVA2.2 subsystem
- Blocking the interrupts and DMA requests to the IVA2.2 on clean boundaries, when the WUGEN is asked to go into IDLE state
- Detecting the enabled wake-up interrupts and DMA requests and generating a wake-up event to the PRCM
- Formatting interrupts to C64x + Megamodule interrupt format

[Figure 1-18](#) shows the WUGEN in the IVA2.2 subsystem and its interactions with other submodules.

**Figure 1-18. IVA2.2 WUGEN Description**

### 1.3.4.1 Interrupts, DMA Requests, and Event Management

Interrupts and DMA requests are generated the same way in the WUGEN module. In this section, both are called events.

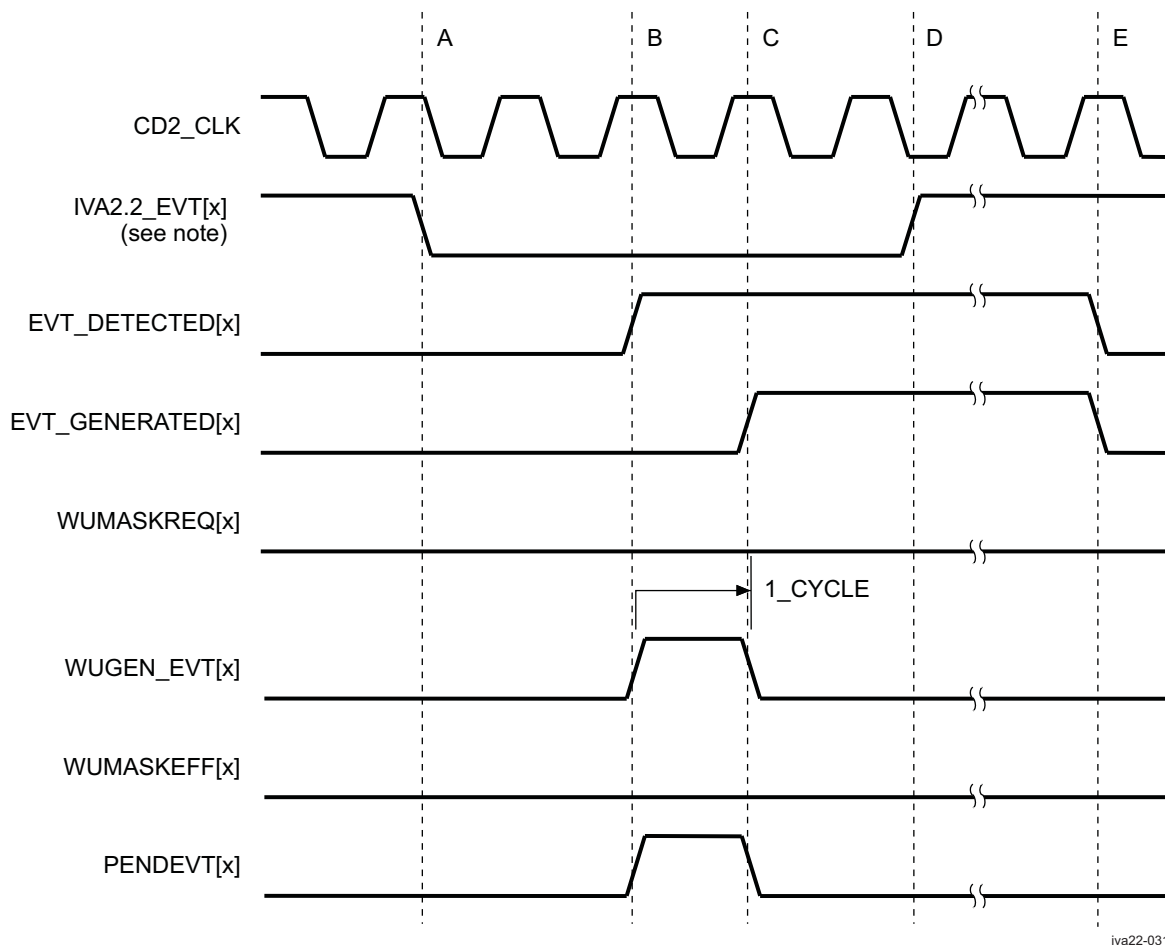

To manage interrupts, DMA requests, and slave port accesses from external modules, the WUGEN module uses several sets of user-programmable registers:

- The WUGEN\_MEVT0, WUGEN\_MEVT1, and WUGEN\_MEVT2 registers define individual mask bits for external asynchronous events (interrupts, DMA requests, slave port access). This register is read-only, only by the DSP. To modify the value of the individual mask, write 1 to the associated bits of WUGEN\_MEVTCLR0, WUGEN\_MEVTCLR1, and WUGEN\_MEVTCLR2 (to clear) and WUGEN\_MEVTSET0, WUGEN\_MEVTSET1, and WUGEN\_MEVTSET2 (to set).
- The WUGEN\_PENDEVT0, WUGEN\_PENDEVT1, and WUGEN\_PENDEVT2 registers are read-only registers that track which external events are pending in the WUGEN module and are not yet generated to the C64x + Megamodule interrupt controller (INTC) or to the EDMA. If an event is masked, this information is stable until the corresponding mask bit is cleared. If an event is unmasked, this information may not be stable, and therefore corresponds to a transitive period of processing the event in the WUGEN module.

### 1.3.4.1.1 Event Generation

Figure 1-19 shows event-generation steps in the WUGEN.

Figure 1-19. WUGEN Event Generation

iva22-031

**Note:** IVA2.2\_EVT[x] refers to either IVA2.2nIRQ[x] or IVA2.2\_nDMAREQ[x].

- An asynchronous event is asserted.
- The event is resynchronized and detected. Because the event is not masked, it is propagated to C64x + Megamodule/EDMA.
- The event-pending flag is cleared because the event was generated. The event to C64x + Megamodule/EDMA is de-asserted after one WUGEN clock cycle.
- After some time, the source of the event is released (probably because it cleared in the corresponding interrupt status register).
- The release of the event is detected and clears the internal EVT\_GENERATED flag for that interrupt.

### 1.3.4.1.2 Individual Event Masking

To mask individual events, write 1 in the WUGEN\_MEVTSET0, WUGEN\_MEVTSET1, or WUGEN\_MEVTSET2 register of the WUGEN module. These registers are used to mask interrupts and DMA requests.

Figure 1-20 shows the mechanism of event masking in the WUGEN module.

**Figure 1-20. WUGEN Event Masking**

iva22-032

**Note:** IVA2.2\_EVT[x] refers to either IVA2.2\_nIRQ[x] or IVA2.2\_nDMAREQ[x].

- The user sets the corresponding bit in the mask. Event generation is disabled.
- Event mask completion is reflected in the IVA2.2.WUGEN\_MEVT0 to IVA2.2.WUGEN\_MEVT2 registers (where i = 0 to 2) for reads.
- An asynchronous event is asserted.
- The event is resynchronized and detected. Because the event is masked, it is not propagated to C64x + Megamodule/EDMA. The event-pending flag is kept active (sticky) until the mask is removed.

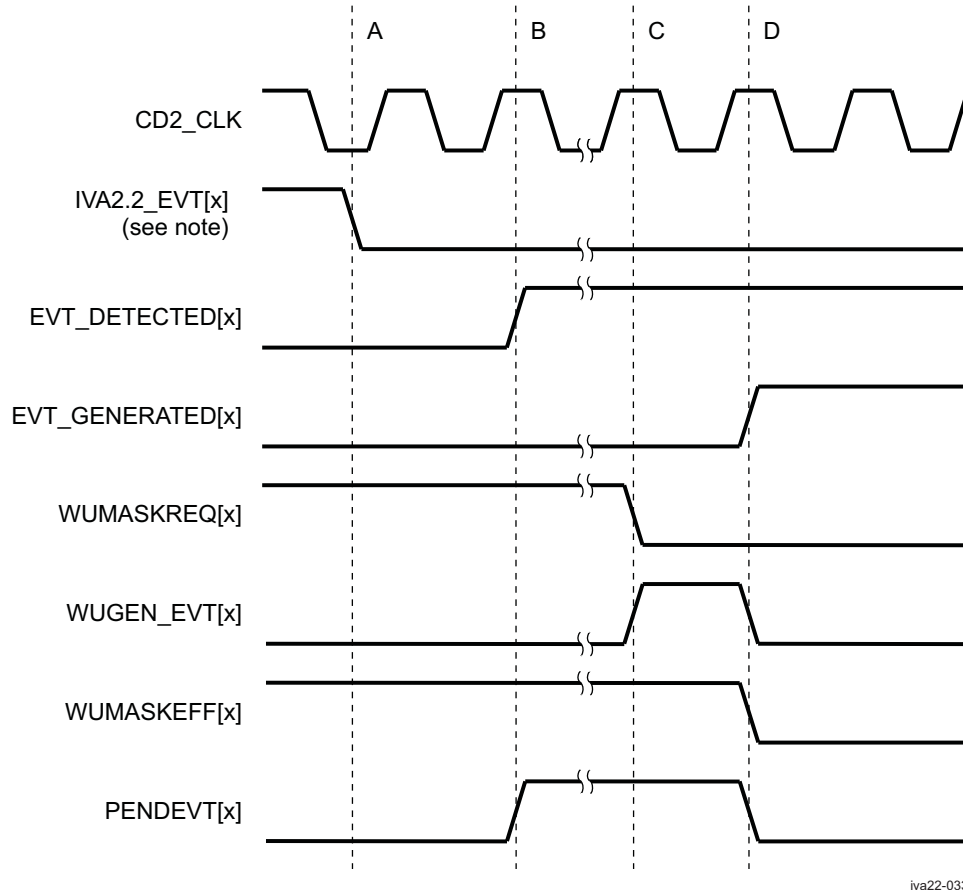

### 1.3.4.1.3 Individual Event Mask Clear

To unmask individual events, write 1 in the WUGEN\_MEVTCLR0, WUGEN\_MEVTCLR1, or WUGEN\_MEVTCLR2 register of the WUGEN module.

Figure 1-21 shows the event-mask-clear mechanism in the WUGEN module.

Figure 1-21. WUGEN Event Mask Clear

iva22-033

**Note:** IVA2.2\_EVT[x] refers to either IVA2.2\_nIRQ[x] or IVA2.2\_nDMAREQ[x].

- An asynchronous event is asserted.
- The event is resynchronized and detected. Because the event is masked, it is not propagated to C64x + Megamodule/EDMA. The event-pending flag is kept active (sticky) until the mask is removed.
- After some time, clear the corresponding bit in the WUGEN mask. The event is automatically generated to C64x + Megamodule if the event is still seen as active. If the event is not seen as active, nothing happens.
- In both cases, the event-pending flag is cleared.

For more information about interrupts and the EDMA programming model, see [Section 1.4.5, Interrupt Management](#), and [Section 1.4.3.1, Transfers From/to Device Memories/Peripherals \(EDMA\)](#).

#### 1.3.4.2 Idle Handshake

After reset, the WUGEN waits for a request. If the user executes the DSP IDLE instruction to put the DSP in standby state, the SYSC initiates a clock-off handshake with the WUGEN.

#### 1.3.5 SYSC Module

The SYSC module of the IVA2.2 subsystem controls the following functions:

- Generation of the divided clocks to all components of the IVA2.2 subsystem
- Synchronization of the IVA2.2 divided clocks and the C64x + Megamodule internal-divided clocks
- PRCM power handshaking

- Sequencing of clock-to-off transition for the IVA2.2 modules
- Reset input resynchronization of the active-to-nonactive transition to the CD2\_CLK clock
- IVA2.2 boot configuration and its access from the DSP

Figure 1-22 is the block diagram of the SYSC in the IVA2.2 subsystem.

**Figure 1-22. SYSC Block Diagram**

**Note:** For more information, see [Section 1.2.1, Clocking, Reset, and Power-Management Scheme](#).

### 1.3.5.1 Divided Clock Generation

The SYSC module generates the divided clocks used by the modules in the IVA2.2 subsystem. The SYSC generates three clocks:

- CD0\_CLK
- CD1\_CLK
- CD2\_CLK

Based on the IVA2.2\_FCLK clock, these three clocks are configured from the PRCM. For details, see [Section 1.2.1, Clocking, Reset, and Power-Management Scheme](#).

### 1.3.5.2 Clock Management, Power-Down, and Wake-Up

The SYSC ensures correct generation of the clocks described in [Figure 1-22](#). The SYSC also allows management of the clock gating of the EDMA, video accelerator, and C64x + Megamodule if the user wants to lead some dynamic power aspects.

The SYSC module controls the transition to IVA2.2 subsystem standby state and standby signal

generation (IVA2.2\_MSTANDBY signal in [Figure 1-22](#)) to the PRCM. Using the signals DSP\_MEGACELL\_STANDBY, EDMA\_STANDBY, VIDEO\_STANDBY, Mx\_IdleReq, and Mx\_IdleAck, the SYSC manages and controls the correct power-down transition of the IVA2.2 subsystem and its submodules to ensure that the IVA2.2 internal clocks can be cut. For information about the IVA2.2 power-down transition and its programming model, see [Section 1.4.7.3, Power-Down and Wake-Up Management](#).

External events can also occur at the IVA2.2 boundary (access to IVA2.2 using the slave access port or external nonmasked events), requiring the restart of the IVA2.2 clocks (in case of IVA2.2 standby state). The WUGEN module controls the asynchronous generation of a wake-up signal to the PRCM; this signal restarts IVA2.2 PLL clock generation, allowing the SYSC to regenerate the IVA2.2 internal clocks.

### 1.3.5.3 Boot Configuration

The IVA\_SYSC.SYSC\_BOOTADDR and IVA\_SYSC.SYSC\_BOOTMOD registers are the boot-time configuration registers. These read-only registers are accessible only by the DSP, and their values are determined when the IVA2.2 subsystem is released from reset by the PRCM.

The values of these registers are driven externally by two system control module registers, SYSC\_GENERAL1.CONTROL\_IVA2\_BOOTADDR and SYSC\_GENERAL1.CONTROL\_IVA2\_BOOTMOD, which are read-write accessible by the MPU subsystem for MPU-driven IVA2.2 boot sequence and/or by the IVA2.2 DSP for autonomous boot. For more information, see [Section 1.4.1, IVA2.2 Boot](#).

---

**Note:** If the values of the SYSC\_GENERAL1.CONTROL\_IVA2\_BOOTADDR and SYSC\_GENERAL1.CONTROL\_IVA2\_BOOTMOD registers change, the new IVA2.2.SYSC\_BOOTADDR and IVA2.2.SYSC\_BOOTMOD register values are not updated until the next reset.

---

For more information, see [Section 1.4.1, IVA2.2 Boot](#).

### 1.3.5.4 Interconnect Optimization

The IVA2.2.SYSC\_LICFG0 and IVA2.2.SYSC\_LICFG1 registers are local interconnect configuration registers. They are read-write accessible by the DSP only. Setting these registers enables or disables interconnect optimization.

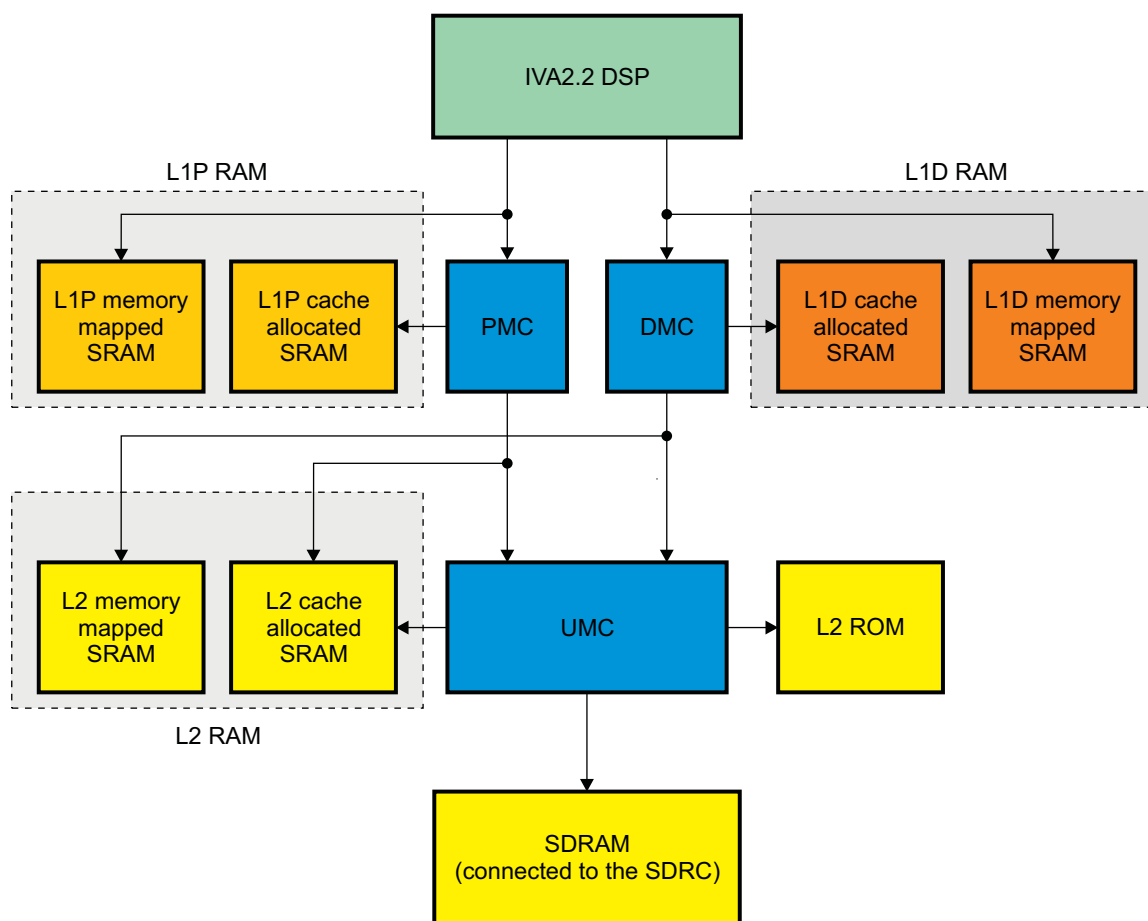

## 1.3.6 Local Memories

The IVA2.2 subsystem integrates three memory controllers under the control of the C64x + Megamodule:

- DMC
- PMC
- UMC

Depending on the software configuration of these memory controllers, the IVA2.2 subsystem local memories (ROM and RAMs) can be used as cache or memory-mapped memories.

[Figure 1-23](#) shows the memory hierarchy of the IVA2.2 subsystem.

**Figure 1-23. IVA2.2 Local Memories Hierarchy**

iva22-035

Table 1-6 lists the IVA2.2 C64x + Megamodule cache controller features.

**Table 1-6. IVA2.2 C64x + Megamodule Cache Controller Features**

Cache	L1 Program Cache	L1 Data Cache	L2 Unified Cache
SIZE	Programmable to 0KB, 4KB, 8KB, 16KB, or 32KB	Programmable to 0KB, 4KB, 8KB, 16KB, or 32KB	Programmable to 0KB, 32KB, or 64KB
ASSOCIATIVITY	Direct-mapped	Two-way set associative	Four-way set associative
SRAM MODE [memory-mapped SRAM]	Programmable to 0KB, 16KB, 24KB, 28KB, 32KB [32KB - cache size]	Programmable to 48KB, 64KB, 72KB, 76KB, 80KB [80KB - cache size]	Programmable to 32KB, 64KB, or 96KB [96KB - cache size]
WRITE BUFFER	NR	Yes	Yes
HIT UNDER MISS	Yes	Yes	No
MISS PIPELINING	Yes	Yes	No
REPLACEMENT POLICY	NR	True LRU	True LRU (pseudo-LRU)
CACHEABILITY	Always cached	Programmable	Programmable
BUFFERABILITY	NR	Always buffered	Always buffered
WRITE POLICY	NR	Always write-back	Always write-back
ALLOCATION POLICY	Read-allocate	Read-allocate	Read-write-allocate
CRITICAL WORD FIRST	No	No	No
CRITICAL LINE FIRST	NR	NR	Yes
ADVANCE FETCH	Yes, because of DSP advanced fetch-and-miss pipelining	NR	NR

### 1.3.6.1 ROM Overview

The IVA2.2 subsystem contains 16KB L2 ROM. The content of this ROM includes boot code.

For information about boot code and the IVA2.2 boot mechanism, see [Section 1.4.1, IVA2.2 Boot](#).

When the L1P SRAM is configured to be inactive (that is, fully memory-mapped SRAM), DSP program fetch accesses to the L2 ROM are realized directly, and thus suffer the L2 latency.

### 1.3.6.2 RAM Overview

- 32KB L1 program RAM (L1P)
- 80KB L1 data RAM (L1D)
- 96KB L2 unified RAM (L2)

---

**Note:** The maximum cache size for the PMC is 32KB. L1P memory-mapped RAM can be programmed to allocate 0KB (full-cache), 16KB, 24KB, 28KB, or 32KB (no cache, default) using the PMC registers. The remaining memory is allocated to the cache controller.

The maximum cache size for the DMC is the default 32K bytes. L1D memory-mapped RAM can be programmed to allocate 48KB (full-cache), 64KB, 72KB, 76KB, or 80KB (no cache, default). The remaining memory is allocated to the cache controller (DMC).

---

L1P and L1D RAM operate at the DSP frequency (CD0 clock domain).

L2 RAM operates at half the DSP frequency (CD1 clock domain).

In the IVA2.2 subsystem, L2 can be configured so that the memory-mapped RAM allocates 32KB, 64KB, or 96KB (no cache) of L2 memory. The remaining memory is allocated to the cache controller.

By default, L2 memory is used as 96-KB local memory-mapped RAM. However, L2 RAM is typically used as 64KB allocated to the cache RAM. This is programmable in the C64x + Megamodule UMC.

The L2 memory-mapped SRAM is shared by the C64x + Megamodule and the SL2 interface. An arbitration mechanism is implemented for concurrent access, with the C64x + Megamodule having priority. These last 32KB cannot be used as cache RAM, but only as memory-mapped RAM.

For information about the software programming model for cache management of the local RAM memories of the IVA2.2 subsystem, see [Section 1.4.2, Cache Management](#).

## 1.3.7 Local Interconnect Network

The local interconnect network is the IVA2.2 internal logic that allows internal communication between the modules of the subsystem (for example, the C64x + Megamodule can communicate with the EDMA or with the WUGEN module). Communication with the rest of the system is through the MMU as master port (accesses from the IVA2.2 subsystem to the L3 interconnect), and through a slave port for accesses from the L3 interconnect (accesses from the L3 interconnect to the IVA2.2 subsystem).

For information about global memory mapping of the IVA2.2 subsystem (DSP CPU view or MPU view through the L3 interconnect), see the *Memory Mapping* chapter.

### 1.3.7.1 Endianness

The IVA2.2 local interconnect network does not support the big-endian convention or any type of endianness conversion. Only little-endian is supported by the local interconnect network.

## 1.3.8 Error Reporting

Several mechanisms are available in the IVA2.2 subsystem to report errors at different levels.

The INTC of the C64x + Megamodule allows reporting of dropped interrupts, through the INTERR signal.

L3 out-of-band errors are also reported through the external L3 interrupt signal. For details about interrupt mapping, see [Table 1-3](#). For information about L3 interconnect error reporting, see the *Interconnect* chapter.

The IDMA and EDMA have their own error-reporting mechanism. Error-status registers and error interrupts inform the user of problems during IVA2.2 internal operation (data error, bus activity error, etc.).

For information about error management and the register set that allows error tracing, see [Section 1.4.8](#), *Error Identification Process*.

## 1.4 IVA2.2 Subsystem Basic Programming Model

### 1.4.1 IVA2.2 Boot

The boot-time configuration registers are IVA\_SYSC.SYSC\_BOOTADDR and IVA\_SYSC.SYSC\_BOOTMOD. These read-only registers are accessible only by the DSP CPU, and their values are determined when the IVA2.2 is released from reset, using the CONTROL.CONTROL\_IVA2\_BOOTADDR and CONTROL.CONTROL\_IVA2\_BOOTMOD registers of the system control module. For more information, see the *System Control Module* chapter. A change to those registers is not seen (not sampled) by the IVA2.2 until the next reset.

The IVA2.2 boots two ways:

- Boot under MPU control, described in [Section 1.4.1.2.1, Boot Under MPU Control](#).
- Autonomous boot, described in [Section 1.4.1.2.2, Autonomous Boot](#).

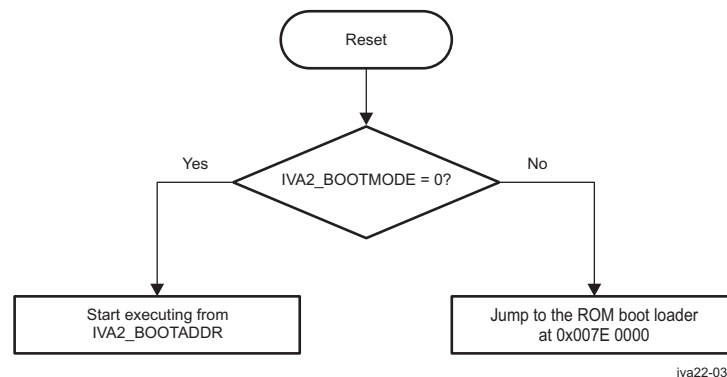

A boot under MPU control is typically used after the device cold reset as a first-time configuration of the IVA2.2 subsystem. Subsequent boots of the IVA2.2, resulting from a wake-up transition from OFF state, for example, use the autonomous boot.

For more information about booting the IVA2.2, see the *IVA2.2 Boot Loader Specification*.

#### 1.4.1.1 IVA2.2 Boot Configuration

[Figure 1-24](#) shows the boot sequence followed by IVA2 on release from reset.

**Figure 1-24. IVA2 Boot Mode Configuration**

When the IVA2.2 subsystem is released from reset and CONTROL.CONTROL\_IVA2\_BOOTMOD[3:0] BootMode equals 0x0, the first fetch address of the C64x equals the address defined in the CONTROL.CONTROL\_IVA2\_BOOTADDR[31:10] BOOTLOADADDR bit field. This address can be aligned on any 1-K byte boundary, in ROM, in IVA2.2 local RAM, in on-chip memory (OCM-RAM), or directly in external memory (for example, SDRAM through the SDRC).

When the IVA2.2 subsystem is released from reset and CONTROL.CONTROL\_IVA2\_BOOTMOD[3:0] BootMode is different from 0x0, the first fetch address of the C64x is fixed to 0x007E0000 (in IVA2.2 local ROM). ROM code (boot-loader) can jump to the address defined in IVA\_SYSC.SYSC\_BOOTADDR[31:12] BOOTLOADADDR, which is a read-only copy (at reset time) of the CONTROL.CONTROL\_IVA2\_BOOTADDR[31:12] BOOTLOADADDR bit field. This address can be aligned on any 4-K byte boundary, in ROM, in local RAM, in on-chip memory, or directly in external memory (for example, SDRAM).

Bits 10 and 11 of the CONTROL\_IVA2\_BOOTADDR BOOTLOADADDR system control module register are ignored in this address alignment.

[Table 1-7](#) lists the boot modes for the boot loader.

**Table 1-7. Boot Loader Configuration**

Value of SYSC_IVA2_BOOTMOD	Description
0x01	IDLE boot: Boot loader executes the IDLE instruction.
0x02	Wait In self-loop boot: Boot loader puts IVA2 in a self-loop.
0x03	Wait In self-loop boot: Boot loader puts IVA2 in a self-loop.
0x04	Boot loader executes the default context restore code, which is part of the ROM boot loader.

For information about the IVA2.2 boot, see the *IVA2.2 Boot Loader Specification*.

### 1.4.1.2 Example of IVA2.2 Boot

#### 1.4.1.2.1 Boot Under MPU Control

Before waking up the IVA2.2 subsystem, the MPU performs the following sequence (also shown in [Figure 1-25](#)):

1. The MPU prepares a translation table hierarchy (TTH) in SDRAM at address <TTH Physical Address>. This TTH must contain at least an address translation for the IVA2.2 MMU physical address range.

---

**Note:** The DSP CPU does not require an address translation for the TTH, as the TTH is under MPU control only. The IVA2.2 DSP CPU is responsible only for saving and restoring an IVA2.2 MMU context that has been programmed by the MPU.

---

2. The MPU writes a bootstrap sequence in SDRAM at address <BootLoader Physical Address>. This sequence is executable by the DSP CPU and contains only relative address references, so that it is relocatable without code modification. This sequence must contain at least (in order):
  - a. Set the size of the bootstrap code.
  - b. Program the IVA2.2 MMU using physical addresses, as described in the following steps.

---

**Note:** The device has two instances of MMU: camera MMU or MMU1 (used for the camera subsystem) and IVA2.2 MMU or MMU2 (used for the IVA2.2 subsystem). These two instances are programmed by two identical sets of configuration registers. For more information, see the *Memory Management Units* chapter.

---

3. Programming of the MMU2 is functionally restricted to setting the MMU2.MMU\_CNTL[1] MMUENABLE bit, and the TLB misses are served by the MPU-dedicated interrupt service routine (ISR). However, MMU table-walking logic is preferred because the IVA2.2 must be autonomous after the preliminary settings.

Moreover, it is critical that the duration of the MMU save-and-restore process use a minimum number of cycles, so that address translation for the MMU configuration registers uses a TLB locked entry. For those reasons, it is recommended that the bootstrap follow the MMU initialization sequence:

- a. Write <TTH physical address>[31:7] to the MMU2.MMU\_TTB[31:17] TTBADDRESS bit field.
- b. Lock the address translation for the MMU configuration registers.
  - i. Write 0x0 to the MMU2.MMU\_LOCK[8:4] CURRENTVICTIM bit field.
  - ii. Write <MMU virtual address>[31:12] to the MMU2.MMU\_CAM[31:12] VATAG bit field.
  - iii. Write 1 to the MMU2.MMU\_CAM[2] V bit.
  - iv. Write 0x2 to the MMU2.MMU\_CAM[1:0] PAGESIZE bit field.
  - v. Write <MMU physical address>[31:12] to the MMU2.MMU\_RAM[31:12] PHYSICALADDRESS bit field.
  - vi. Write 1 to the MMU2.MMU\_LD\_TLB[0] LDTLBITEM bit.
  - vii. Write 0x1 to the MMU2.MMU\_LOCK[8:4] CURRENTVICTIM bit field.
  - viii. Write 0x1 to the MMU2.MMU\_LOCK[14:10] BASEVALUE bit field.
- c. Write 1 to the MMU2.MMU\_CNTL[2] TWLENABLE bit.
- d. Write 1 to the MMU2.MMU\_CNTL[1] MMUENABLE bit.
- e. Read back the MMU2.MMU\_CNTL register to ensure write completion.

**Note:** This read does not generate a TLB miss, because the address translation for MMU configuration registers is locked in the TLB.

4. The MPU can lock some other TLB entries, define some power-management MMU settings, and/or enable some interrupts.
5. The MPU correctly programs the associated L3 firewall, ensuring that the DSP CPU has read access to the memory area containing the IVA2.2 bootstrap sequence.
6. The MPU programs the associated L3 firewall, ensuring that the DSP CPU has read and write access to the configuration registers of the MMU2.
7. The MPU writes <bootloader physical address> to the CONTROL.CONTROL\_IVA2\_BOOTADDR[31:10] BOOTADDR bit field and configures the correct CONTROL.CONTROL\_IVA2\_BOOTMOD[3:0] BOOTMOD bit field nonzero value.

**Note:** For a detailed description of the system boot registers, see the *System Control Module* chapter.

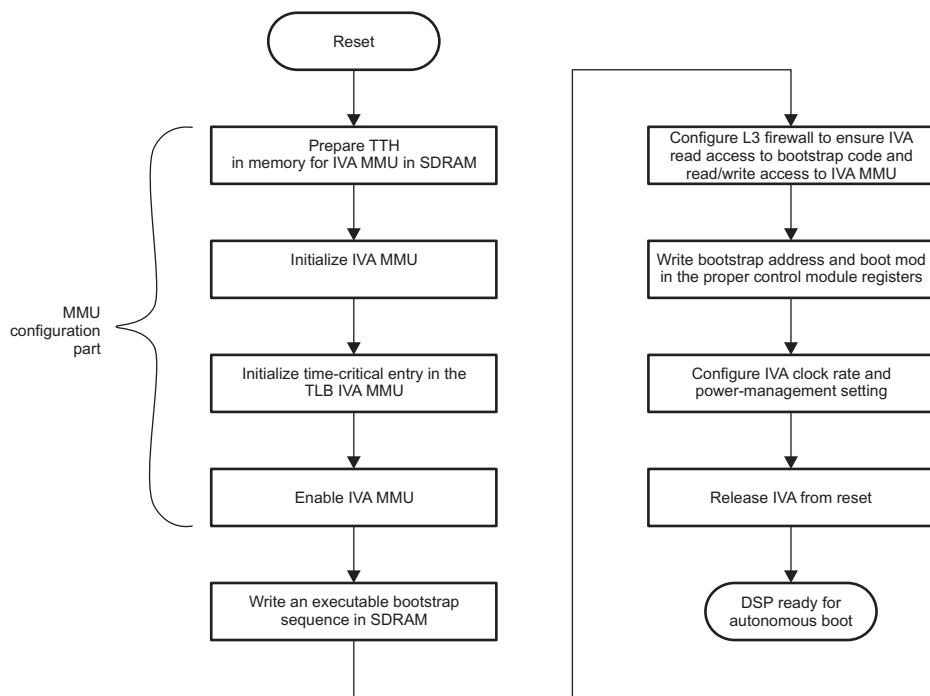

8. The MPU configures the IVA2.2 clock rate and IVA2.2-related power-management settings in the PRCM.

After initialization completes, the MPU allows the IVA2.2 to boot:

- a. The MPU releases the IVA2.2 from the OFF state by programming the PRCM.
- b. The MPU sets the clocks back to the IVA2.2.
- c. The MPU releases the IVA2.2 from reset.

**Note:** Following Steps 1 through 8, the IVA2.2 boot sequence is identical to the autonomous boot sequence. For information about the IVA2.2 boot sequence, see [Section 1.4.1, IVA2.2 Boot](#).

**Figure 1-25. IVA2 Boot Basic Programming Model**

iva22-037

### 1.4.1.2.2 Autonomous Boot

On an OFF-to-ACTIVE transition (under MPU control or upon interrupt wakeup), the IVA2.2 subsystem is released from reset.

After hardware configuration of values for C64x + Megamodule generic parameters, the IVA2.2 starts fetching from the address 0x00000000 in ROM. The IVA2.2 must follow the (nonexhaustive) boot process:

1. Configure memory protection:
  - a. Specify cache RAMs versus IDMA and DMA accesses.
  - b. Define accessible L2 space (static shared L2 with the MPU/LCD).
2. Load the bootstrap code:
  - a. Read the IVA\_SYSC.SYSC\_BOOTADDR[31:12] BOOTLOADADDR bit field.
  - b. Read the number of bootstrap words <NbOfWords> to transfer in the first word at the address pointed to by BOOTLOADADDR.
  - c. Transfer as many words as defined in <NbOfWords>.
3. Execute the bootstrap code.

---

**Note:** This prepares the MMU for address translation of external accesses. In the case of a boot upon interrupt wakeup, the MMU is restored to its exact context before the IVA2.2 is shut off, if this context was saved correctly.

Only from this point can the IVA2.2 subsystem work with virtual addresses.

---

## 1.4.2 Cache Management

The IVA2.2 subsystem has a 2-level cache-based architecture. Level 1 data memory/cache (L1D) consists of an 80-KB memory space dedicated to data. L1D memory can be configured as mapped memory, cache, or a combination of the two. The level 1 program memory/cache (L1P) consists of a 32-KB memory space dedicated to program instructions. L1P memory can be configured as mapped memory, cache, or a combination of the two. Level 2 memory/cache (L2) consists of a 96-KB memory space shared by program and data space. L2 memory can be configured as mapped memory, cache, or a combination of the two.

Configuration of the allocation of the L1D, L1P, and L2 memories to mapped memory and/or cache is described in [Section 1.4.2.1, Cache-Size Configuration](#).

The virtual address space is split into contiguous chunks to configure which parts of the memory are cacheable and not cacheable. Configuration of cacheability is described in [Section 1.4.2.3, Cacheability Settings](#).

### 1.4.2.1 Cache-Size Configuration

Cache-size configuration is controlled by a set of registers: IVA\_XMC.L1PCFG, IVA\_XMC.L1DCFG, and IVA\_XMC.L2CFG, that correspond to the L1P, L1D, and L2 memories, respectively.

The IVA\_XMC.L1PCFG register allows the selection of the size of the L1P cache. The user selects the size of the L1P cache by writing the requested mode to the L1PCFG[2:0] L1PMODE bit field.

[Table 1-8](#) lists the valid settings of L1PMODE.

**Table 1-8. Cache Size Specified by L1PMODE**

L1PCFG[2:0] L1PMODE	Amount of L1P
Setting	Cache
000b	0 KB (default)
001b	4KB
010b	8KB
011b	16KB

**Table 1-8. Cache Size Specified by L1PMODE (continued)**

L1PCFG[2:0] L1PMODE	Amount of L1P
100b	32KB
101b	Not used
110b	Not used
111b	Maximum cache (maps to 32KB)

The IVA\_XMC.L1DCFG register allows the selection of the size of the L1D cache. The user selects the size of the L1D cache by writing the requested mode to the L1DCFG[2:0] L1DMODE bit field.

Table 1-9 lists the valid settings of L1DMODE.

**Table 1-9. Cache Size Specified by L1DMODE**

L1DCFG[2:0] L1DMODE	Amount of L1D
Setting	Cache
000b	0KB (default)
001b	4KB
010b	8KB
011b	16KB
100b	32KB
101b	Not used
110b	Not used
111b	Maximum cache (maps to 32KB)

In the same way, the L2CFG[2:0] L2MODE bit field controls the size of the L2 cache. The user sets the amount of L2 memory mapped as L2 cache by writing the desired cache mode to this bit field.

Table 1-10 shows the valid settings for L2MODE.

**Table 1-10. Cache Size Specified by L2MODE**

L2CFG[2:0] L2MODE	Amount of L2
Setting	Cache
000b	0KB (default)
001b	32KB
010b	64KB

When programs initiate a cache mode change, the L1D cache must write back and invalidate its current contents without losing data. This ensures that all updated data held in cache is written back, and that no false hits occur because of a change in the interpretation of cache tags. It also ensures that the L1D snoop tag RAM in the UMC stays in sync with L1D.

While the write-back-invalidate is required to ensure correct cache behavior and to ensure that no cached data is lost, it is not sufficient to prevent data loss as a result of portions of L1D RAM becoming cache. To safely change L1D cache modes, applications must adhere to the procedure described in Table 1-11.

**Table 1-11. Switching Cache Modes**

To switch from	To	The program must perform the following steps:
A mode with no or some cache	A mode with more cache	1: EDMA, IDMA, or copy necessary data out of the affected range of RAM.  2: Write the desired cache mode to the bit field in the configuration cache register (L1DCFG, L1PCFG, and L2CFG).  3: Read back the register to stall the DSP CPU until the mode change completes.
A mode with some cache	A mode with less or no cache	1: Write the desired cache mode to the bit field in the cache configuration register concerned.

**Table 1-11. Switching Cache Modes (continued)**

To switch from	To	The program must perform the following steps:
		2. Read back the register to stall the DSP CPU until the mode change completes.

L1P RAM is typically used as cache RAM, with no local flat RAM (not the default; must be configured by the user).

L1D RAM is typically used as 32KB allocated to the cache RAM and 48KB has local memory-mapped RAM. By default, L2 memory is configured as 0KB allocated to the cache RAM and 96KB as local memory-mapped RAM (see [Table 1-12](#)).

**Table 1-12. Default Cache Configuration**

Memory Type	Memory Size	Default Cache Setting
L1P RAM	32KB	0KB cache
L1D RAM	80KB	0KB cache
L2 RAM	96KB	0KB cache

### 1.4.2.2 Cache Mode Configuration

The memory cache controllers of the C64x + Megamodule (L1D, L1P, and L2) offer two additional operating modes: freeze and/or bypass. These modes are set by the L1DCC[2:0] OPER bit field for L1D, the L1PCC[2:0] OPER bit field for L1P, and the L2CFG[4:3] L2CC bit field for L2.

The freeze and bypass modes affect the operation of only the cache section (no impact on the memory-mapped section of the memory) of each memory controller.

This feature allows real-time applications to limit the amount of data evicted from cache controllers, such as interrupt handlers, during various sections of code.

[Table 1-13](#) summarizes the freeze and bypass modes for each cache controller (set through the OPER field in the L1PCC register for the L1P cache controller, the OPER field in the L1DCC register, and the L2CC field of the L2CFG register for the L2 cache controller).

**Table 1-13. Cache Mode Configuration**

Cache Controller	Operation Mode		
	Normal	Freeze	Bypass
L1P	Cache operates normally. Read hits return data from the cache. Write hits update the cached data for the cache line.	<p>The L1P cache does not allocate new cache lines on read misses, nor does it cause existing cache contents to be marked invalid. Write misses are dropped.</p> <p>The L1P cache responds normally to program-initiated cache controls (invalidate, mode change).</p>	N/A
L1D	Cache operates normally.	<p>The L1D cache does not allocate new cache lines on read misses, nor does it evict existing cache contents.</p> <p>The L1D cache responds normally to program-initiated cache commands (invalidate, write-back-invalidate mode change).</p>	N/A

**Table 1-13. Cache Mode Configuration (continued)**

Cache Controller	Operation Mode		
	Normal	Freeze	Bypass
L2	Cache operates normally.	Cache frozen. Hits proceed normally. L2 sends read and write misses directly to external memory, as if the L2 cache is not present. The L2 does not allocate a new cache line while frozen. Lines can be evicted from L2 only during freeze mode by program-initiated cache coherence operations.	Cache disabled, although internal cache state is retained. When in bypass mode, the L2 cache responds to neither reads nor writes. All requests for external addresses are sent externally. L2 does not update its contents in this mode. As with freeze mode, L2 evicts lines from L2 only during bypass mode as a result of program-initiated cache coherence operations.

### 1.4.2.3 Cacheability Settings

The address space of the IVA2.2 subsystem is split into contiguous regions of 16M bytes each. Each region has a cacheable attribute that defines whether a reference to a location belonging to the associated memory region must be sent directly to the memory (with exact size and occurrence as requested by the CPU) or must induce a cache line refill and potentially an eviction of another cache line.

The UMC contains registers that control whether certain ranges of memory are cacheable, and whether one or more requestors is allowed access to these ranges.

### 1.4.2.4 Coherence Maintenance

#### 1.4.2.4.1 Memory-Mapped L1P and L1D Coherence

L1D and L1P are never cached, so there is no coherence maintenance for those memories.

#### 1.4.2.4.2 Memory-Mapped L2 Coherence

Coherence is maintained by hardware between L1D cache content and the L2 memory-mapped memory region.

An L2 reference from the DSP CPU updating an L1D cache location is automatically made visible to the DMA and any master processor on the device with access to the C64x + Megamodule memory-mapped L2 through the IVA2.2 slave port.

An L2 reference from the DMA and any other master processor on the device with access to the C64x + Megamodule memory-mapped L2 through the IVA2.2 subsystem slave port is automatically made visible to the DSP CPU through the L1D cache, if it is holding the associated cache line.

**Note:** To reduce the complexity of the L1P cache controller to the L2 controller interface, the L1P cache coherency protocol is removed. This means that coherency between L2 cache and L1P cache is not maintained. On the C64x+ CPU, writes to L2 do not invalidate the corresponding region in L1P. This must be done manually.

#### 1.4.2.4.3 Device Memory Coherence

Coherence is not maintained by hardware between the L2 cache (and L1D cache/L1P cache) and device memories (on-chip memories external to the IVA2.2 subsystem and off-chip memories connected to the SDRAM controller and/or general-purpose memory controller [GPMC]). Coherence in this case must be handled by software. The C64x + Megamodule offers two sets of registers for user-initiated coherence maintenance between DSP local memories and device memories.

Software coherence maintenance must be synchronized in the system (for example, through message passing; for information, see the *Interprocessor Communication* chapter). In the producer/consumer

model, the producer sends a completion message to the consumer only after the write is complete in end memory. If the producer has a cache-based architecture, the producer must initiate a write-back and track for the completion of the write-back sequence in end memory. For a description of how the write-back sequence occurs in the IWA2.2 subsystem, see [Section 1.4.2.4.6, Write-Back Completion](#). When the consumer receives the message, if the consumer has a cache-based architecture, updates by the producer must be effectively seen (not a local nonupdated copy). For a description of how the invalidate sequence occurs in the IWA2.2 subsystem, see [Section 1.4.2.4.4, Global Cache Management](#).

Two types of cache coherence management are possible:

- Global cache coherence allows the DSP CPU to ensure coherence of the entire cache at once. See [Section 1.4.2.4.4, Global Cache Management](#).
- Block cache coherence allows the DSP CPU to ensure coherence of a contiguous region of the virtual address map, restricted in size to only what is needed. See [Section 1.4.2.4.5, Block Cache Management](#).

Each management type provides three sets of actions:

- Invalidate ensures that all required lines are made invalid in the cache. After that operation, any update (before invalidate operation) in end memory by an alternate processor/DMA is seen by the DSP CPU, forcing a cache line refill.
- Write-back ensures that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory, so that any local update by the DSP CPU is made visible by an alternate processor/DMA. This applies only to L1D cache and L2 cache, not to L1P cache.
- Write-back and invalidate ensure that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory so that any local update by the DSP CPU is made visible by an alternate processor/DMA, and they ensure that all required lines are made invalid in the cache. After that operation, any update in end memory by an alternate processor/DMA is seen by the DSP CPU, forcing a cache line refill. This applies only to L1D cache and L2 cache, not to L1P cache.

#### 1.4.2.4.4 Global Cache Management

This section describes how to invalidate and write back the cache memory

- Global invalidate  
Global invalidate is controlled by the following registers: IVA\_XMC.L2INV, IVA\_XMC.L1DINV, and IVA\_XMC.L1PINV.

Example of global invalidate:

```
/* -----
   */
/* Invalidate anything held in cache. */
/* -----
   */

L2INV = 1;
/* -----
   */
/* Now, spin waiting for operation to complete. */
/* -----
   */

while ((L2INV & 1) != 0)
;
```

L2INV = 0 ensures that L1D cache and L1P cache are also globally invalidated before the L2 cache invalidate process.

- Global write-back  
Global write-back is controlled by the following registers: IVA\_XMC.L2WB and IVA\_XMC.L1DWB.  
Example of global write-back:

```
/* -----
   */
/* Write back anything held in cache. */
/* -----
```

```

        */
L2WB = 1;
/* -----
        */
/* Now, spin waiting for operation to complete. */
/* -----
        */
while ((L2WB & 1) != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 1.4.2.4.6, Write-Back Completion](#), for additional programming steps and an example.

- Global write-back and block invalidate

Global write-back and block invalidate is controlled by the following registers: IVA\_XMC.L2WBINV and IVA\_XMC.L1DWBINV.

Example of global write-back and block invalidate:

```

/* -----
        */
/* Write back and invalidate anything held in cache.
        */
/* -----
        */
L2WBINV = 1;
/* -----
        */
/* Now, spin waiting for operation to complete. */
/* -----
        */
while ((L2WBINV & 1) != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 1.4.2.4.6, Write-Back Completion](#), for additional programming steps and an example.

#### 1.4.2.4.5 Block Cache Management

- Block invalidate

Block invalidate is controlled by the following registers: IVA\_XMC.L2BAR, IVA\_XMC.L2IWC, IVA\_XMC.L1DIBAR, IVA\_XMC.L1DIWC, IVA\_XMC.L1PIBAR, and IVA\_XMC.L1PIWC.

Example of block invalidate:

```

/* -----
        */
/* Write base address of array to Base Address Register.
        /
/* Then write length of the array, in words, to the
        Word*/
/* Count register. */
/* -----
        */
L2IBAR = &array[0];
L2IWC = = sizeof(array) / sizeof(int);
/* . . . */
/* -----
        */
/* The CPU can execute other code here. Block cache
        operations proceed in parallel with CPU execution, stalling the
        CPU minimally. */
/* -----
        */
/* . . . */

```

```

/* -----
    */
/* Now, spin waiting for operation to complete. */
/* -----
    */
while (L2IWC != 0)
;
    L2IWC = 0 ensures that L1D cache and L1P cache are also block invalidated before the L2 cache
    invalidate process.

```

- **Block write-back**

Block write-back is controlled by the following registers: IVA\_XMC.L2WBAR, IVA\_XMC.L2WWC, IVA\_XMC.L1DWBAR, and IVA\_XMC.L1DWWC.

Example of block write-back:

```

/* -----
    */
/* Write base address of array to Base Address
    Register.*/
/* Then write length of array, in words, to the Word
    */
/* Count register. */
/* -----
    */
L2WBAR = &array[0];
L2WWC = sizeof(array) / sizeof(int);
/* . . . */
/* -----
    */
/* CPU can execute other code here. Block cache operations
    proceed in parallel with CPU execution, stalling CPU minimally.
    */
/* -----
    */
/* . . . */
/* -----
    */
/* Now, spin waiting for operation to complete. */
/* -----
    */
while (L2WWC != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 1.4.2.4.6, Write-Back Completion](#), for additional programming steps and an example.

- **Block write-back and invalidate**

Block write-back and invalidate is controlled by the following registers: IVA\_XMC.L2WIBAR, IVA\_XMC.L2WIWC, IVA\_XMC.L1DWIBAR, and IVA\_XMC.L1DWIWC.

Example of block write-back and invalidate:

```

/* -----
    */
/* Write base address of array to Base Address
    Register.*/
/* Then write length of array, in words, to the Word
    */
/* Count register. */
/* -----
    */
L2WIBAR = &array[0];
L2WIWC = (array) / sizeof(int);

```

```

/* . . . */
/* -----
    */

/*The CPU can execute other code here. Block cache
   operations proceed in parallel with CPU execution, stalling the
   CPU minimally. */

/* -----
    */

/* . . . */
/* -----
    */

/* Now, spin waiting for operation to complete. */
/* -----
    */

while (L2WIWC != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 1.4.2.4.6](#) for additional programming steps and an example.

#### 1.4.2.4.6 Write-Back Completion

The SYSC\_LICFG0[15] GEMTRUECOMPEN bit must be set to 1 before any DSP CPU C64x+ write for which completion must be ensured. This applies to writes to noncacheable regions and to cache-line write-back completions. By default, SYSC\_LICFG0[15] GEMTRUECOMPEN = 0. This default is recommended, to statically set that bit (unless the user wants to locally send a large number of writes to a noncacheable memory region):

- SYSC\_LICFG0.GEMTRUECOMPEN = 1;

Polling on the L\*WWC (resp. L\*WIWC) ensures that the block write-back operation (and associated invalidate, when applicable) was completely issued by the associated cache controller, but does not ensure that the write-back is effective in end memory.

To get completion of the write-back of a specific buffer after block or global cache write-back, the user must read back from a noncacheable region of the same L3 or L4 target as the buffer (if data is written in external DDR memory, the read access can be on an SDRC register). The C64x+ is uninstalled only after the read following the write-back is complete.

In the producer/consumer model, the cache-based producer typically ensures that the produced buffer is visible to the consumer of that buffer by writing back the address range of that buffer and checking for completion of the write-back sequence before sending a completion message to the consumer.

Example:

```

/* -----
    */

/* nonCachedArea to be linked to noncached SDRAM
   region*/
/* -----
    */

#pragma DATA_SECTION(nonCachedDummyVar, ".nonCachedArea")
volatile int nonCachedDummyVar;
/* -----
    */

/* outBuffer is produced buffer in SDRAM to be visible to
   the consumer */
/* -----
    */

L2WBAR = &outBuffer[0];
L2WWC = sizeof(outBuffer) / sizeof(int);
/* -----
    */

/* L2WWC ensures the sequence is completed by the cache
   controller but not completed in end memory */

```

```

/* -----
    */
while (L2WWC != 0)
;
/* -----
    */
/*C64x+ is stalled until dummy memory read has completed
  which the hardware ensures happens after write-back of outBuffer
  completed in SDRAM. */
/* -----
    */
int dummyRead = nonCachedDummyVar;
/* -----
    */
/* Then C64x SW (producer) can send message to consumer
    */
/* -----
    */

```

- sendCompletionMsgToConsumer();

---

**Note:** To ensure completion, the nonCachedDummyVar must be in the same target as the written-back buffer.

---

In the case of the C64x writing in the noncache area: To ensure the completion of the C64x write in physical end memory, set the SYSC\_LICFG0 [15] GEMTRUECOMPEN bit to 1 and also read back after the last C64x write.

#### 1. DSP write and DMA read

The user writes to some noncache region with DSP and then reads from the same area with DMA. To ensure completion of the DSP write in physical end memory, set the SYSC.LICFG0[15] GEMTRUECOMPEN bit to 1 and also read back after the last DSP write. The sequence is:

- Set the SYSC\_LICFG0[15] GEMTRUECOMPEN bit to 1.
- DSP writes data in external memory, noncache area.
- DSP reads data in external memory, noncache area: last write data for instance.
- DMA reads data from external memory.

#### 2. DMA write and DSP read

The opposite of 1. To ensure the completion of DMA write in physical end memory, set the SYSC\_LICFG0 DMATRUERCOMPEN bit to 1 and PARAM [LCHi].OPT.TCCMODE to 0 (no early completion). The sequence is:

- Set the SYSC\_LICFG0.DMATRUERCOMPEN bit to 1.
- Set PARAM[LCHi].OPT.TCCMODE to 0.
- Set PARAM[LCHi].OPT.TCCMODE to 0.
- DSP waits for end of DMA transferred:
  - IPR/IPRH bit update (for polling-scheme)
  - Interrupt generation (for interrupt-scheme)
  - CER/CERH bit update (for chaining)
  - DSP reads data from external memory.

#### 1.4.2.4.7 Performance Consideration Timing

Long burst is key to improving the efficiency of the SDRAM and reducing cache-line refill and cache-line write-back latencies. The IVA2.2 subsystem allows for improving the burst generation over the device interconnect. This is configurable with the SYSC\_LICFG0[16].GEMBURSTOPTEN bit. By default, SYSC\_LICFG0[16] GEMBURSTOPTEN = 0, and the burst optimization is disabled. This default is recommended to statically set the bit:

SYSC\_LICFG0.GEMBURSTOPTEN = 1

### 1.4.3 DMA Management

#### 1.4.3.1 Transfers From/to Device Memories/Peripherals (EDMA)

The EDMA optimizes transfers from/to the C64x + Megamodule (memory-mapped) memories to/from device on-chip and off-chip memories.

The EDMA can perform transfers from IVA2.2 internal memories to IVA2.2 internal memories, but it is not designed for that purpose. The IDMA is recommended in that case (unless a 2-dimensional transfer is required).

The EDMA can perform transfers from device memories/peripherals to device memories/peripherals, but it is not designed for that purpose. The sDMA is recommended in that case. For more information, see the *DMA* chapter.

#### 1.4.3.2 Internal Memory-to-Memory Transfer (IDMA)

The user can quickly page memory regions or fill a memory region of the C64x + Megamodule memories by using channel 1 of the IDMA module (internal to the C64x + Megamodule).

The IDMA.IDMA1\_COUNT[16] FILL bit defines whether this is a transfer from memory to memory or if this is a solid-color fill.

An IDMA1 transfer where IDMA.IDMA1\_COUNT[16] FILL = 0 copies IDMA.IDMA1\_COUNT[15:2] COUNT bytes from the address defined in the IDMA.IDMA1\_SOURCE register to the address defined in the IDMA.IDMA1\_DEST register. The addresses must be aligned on word (4-byte) boundaries. The byte count must be a multiple of 4 bytes.

The IDMA.IDMA1\_COUNT[28] INT register bit enables the IDMA\_INT1 interrupt (Evt 14; for information about generation on completion of the IDMA1 transfer, see [Table 1-3](#)). By default, no interrupt is generated.

When conflicts occur, the IDMA.IDMA1\_COUNT[31:29] PRI bit field defines the priority of the IDMA transfer with respect to DSP and DMA/HOST accesses.

The memory paging programming example follows:

- IDMA1\_SOURCE = &mySrcTable[0]; // mySrcTable aligned on word boundary
- IDMA1\_DEST = &myDstTable[0]; // myDstTable aligned on word boundary
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(0xFFFC)) | size of (mySrcTable);
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(116)) | 016; // copy mode
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(128)) | 028; // no interrupt
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(0x729)) | 0x729; // low priority

An IDMA1 transfer where IDMA.IDMA1\_COUNT[16] FILL = 1 replicates the IDMA.IDMA1\_SOURCE word as many times as defined in IDMA. An IDMA1\_COUNT.COUNT (count divided by 4) to the address defined in the IDMA.IDMA1\_DEST destination address must be aligned on word (4-byte) boundaries. The byte count must be a multiple of 4 bytes.

The solid-color copy (SSC) programming example follows:

- IDMA1\_SOURCE = my32bPattern; // 32b pattern to be replicated
- IDMA1\_DEST = &myDstTable[0]; // myDstTable aligned on word boundary
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(0xFFFC)) | size of (mySrcTable);
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(116)) | 116; // SCC mode
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(128)) | 028; // no interrupt
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(0x729)) | 0x729; // low priority

---

**Note:** Because the IVA2.2 subsystem is typically configured (recommended for video applications) so that L1D has memory-mapped SRAM, IDMA1 is normally used only for L1D>L1D fast copy.

---

### 1.4.3.3 Programming an EDMA Transfer

Programming a complete EDMA transfer requires the following steps:

1. Define the logical channel(s).
2. Prioritize the defined transfer (with respect to other defined transfers).
3. Start the transfer.
4. Review the progression and completion of the transfer.

### 1.4.3.4 Defining a Logical Channel

#### 1.4.3.4.1 Single Logical Channel Definition

A complete EDMA transfer can be defined by one or several chained and/or linked logical channels.

Up to 128 independent contexts, each fully defining a logical channel, can be defined. These 128 contexts correspond to the 128 PaRAM entries available in the IVA2.2 subsystem. For more information about these PaRAM entries, see [Section 1.3.2.1.1.3, DMA/QDMA Channel Mapping and PaRAM Entry](#), and the corresponding [Figure 1-13](#).

Logical channel definition relies on the following:

- Base addresses:
  - PARAM[LCH#].SRCi: 32-bit source address
  - PARAM[LCH#].DSTi: 32-bit destination address
- Transfer sizes:
 

Transfer size is common to source and destination. A transfer can be constituted on a 3-dimensional array; C is an array of CCNT arrays, each composed of BCNT arrays, each composed of ACNT bytes:

  - PARAM[LCH#].ACNT: Number of bytes in the A array (from 0 to 65,535)
  - PARAM[LCH#].BCNT: Number of A arrays in the B array (from 0 to 65,535)
  - PARAM[LCH#].CCNT: Number of B arrays in the C array (from 0 to 65,535)

---

**Note:** Setting one of the ACNT, BCNT, or CCNT arrays to 0x0 prevents a transfer from being submitted to one of the physical channels (assuming that the compatibility mode is not set; see Kelvin DMA compatibility mode).

---

- PARAM[LCH#].BCNTRLD: BCNT reload value when BCNT reaches 0 (from 0 to 65,535)
- 

**Note:** When programming CCNT>1, programming PARAM[LCH#].BCNTRLD to be equal to PARAM[LCH#].BCNT is recommended.

---

- Indexes between dimensions:
    - PARAM[LCH#].SRCBIDX: Index between A arrays at source (from -32,768 to 32,767)
    - PARAM[LCH#].SCRCIDX: Index between B arrays at source (from -32,768 to 32,767)
    - PARAM[LCH#].DSTBIDX: Index between A arrays at destination (from -32,768 to 32,767)
    - PARAM[LCH#].DSTCIDX: Index between B arrays at destination (from -32,768 to 32,767)
- 

**Note:** Programming the logical channel does not automatically start it. See [Section 1.4.3.6.1, Assigning a Logical Channel to a Trigger Event](#).

---

- Addressing modes:
  - PARAM[LCH#].OPT[0] SAM: source addressing mode (0: post-incremented; 1: constant)
  - PARAM[LCH#].OPT[1] DAM: destination addressing mode (0: post-incremented; 1: constant)

---

**Note:** Constant addressing mode is supported only from/to IVA2.2 C64x + Megamodule memories, not from/to device memories and peripherals. This can be replaced by using a post-increment addressing mode and an index equal to 0.

---

Example:

```

/* -----
   */
/*fills dstArray with cstValue values (w/o constant AM)
   */
/* -----
   */

PARAM[LCH#].SRC = &cstValue;
PARAM[LCH#].DST = &dstArray[0];
PARAM[LCH#].ACNT = sizeof(int);
PARAM[LCH#].BCNT = sizeof(dstArray) / sizeof(int);
PARAM[LCH#].CCNT = 1;
PARAM[LCH#].SRCBIDX = 0;
PARAM[LCH#].DSTBIDX = sizeof(int);
PARAM[LCH#].OPT.SAM = 0;
PARAM[LCH#].OPT.DAM = 0;

```

#### 1.4.3.4.2 Controlling Submission Granularity

The logical channel (when triggered) can split a transfer into several requests submitted to one of the physical channels. The physical channel supports submitted requests of up to two dimensions, meaning that a 3-dimensional transfer is always split into (at least) 2-dimensional transfers. The user can also program the logical channel so that submitted requests are 1-dimensional transfers; for example:

- PARAM[LCH#].SYNCDIM = 0; // submitted transfers are maximum 1D.
- PARAM[LCH#].SYNCDIM = 1; // submitted transfers are maximum 2D.

#### 1.4.3.4.3 Linking to Another Logical Channel

A logical channel can be programmed so that on its completion another context is copied from another logical channel. This is useful because the logical channel is used as a working set during the DMA transfer, meaning that initial context configuration is lost after the associated transfer completes.

- PARAM[LCH#].LINK = linkLCH# << 5

The LINK value is the base address of the linked logical channel context.

When the LINK value is set to 0xFFFF, no context is loaded for that logical channel:

- PARAM[LCH#].LINK = -1

---

**Note:** Only the context is copied, and the logical channel is not automatically restarted on link. Restarting a logical channel that just received its new context occurs only after a trigger event associated with that logical channel is detected. See [Section 1.4.3.6.1, Assigning a Logical Channel to a Trigger Event](#).

---

#### 1.4.3.4.4 Chaining Logical Channel

A logical channel can be programmed so that on its total or partial completion, another logical channel is started. This is useful for defining a series of transfers with different contexts as a complete DMA transfer. The main advantage is that the overhead to program all the chained transfers is shared among all channels.

- Partial completion chaining  
After the submitted section (see [Section 1.4.3.4.2, Controlling Submission Granularity](#)) of a logical channel is complete, a programmable completion code is returned. If partial completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See [Section 1.4.3.6.1, Assigning a Logical Channel to a Trigger Event](#).  
To chain a logical channel LCHi to LCHj, so that LCHj is automatically started after each LCHi submission to a physical channel has completed:
  - PARAM[LCHi].OPT.TCC = trigEvtX; // trigEvtX: trigger event number
  - PARAM[LCHi].OPT.ITCCHEN = 1
  - DCHMAP[trigEvtX] = LCHj
- Total completion chaining  
After all submitted parts of a logical channel are complete, programmable completion code is returned. If total completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See [Section 1.4.3.6.1, Assigning a Logical Channel to a Trigger Event](#).  
For example, to chain a logical channel LCHi to LCHj so that LCHj is automatically started after LCHi has completed:
  - PARAM[LCHi].OPT.TCC = trigEvtX; // trigEvtX: trigger event number
  - PARAM[LCHi].OPT.TCCHEN = 1
  - DCHMAP[trigEvtX] = LCHj

### 1.4.3.5 Prioritizing Defined Transfers

#### 1.4.3.5.1 Mapping Between DMA/QDMA Events and Event Queues

The assignment of 64 DMA and 8 QDMA channels to two event queues of the channel controller is achieved by configuring the DMA queue number registers (TPCC\_DMAQNUM0 and TPCC\_DMAQNUM1) and the QDMA queue number register (IVA\_TPCC.QDMAQNUM). When an event is selected for submission, it is queued in the user-defined event queue. This typically defines a 2-level priority preemption scheme, as queues are usually mapped to different transfer controllers.

#### 1.4.3.5.2 Mapping a Queue to a Transfer Controller

Events at the head of an event queue define which logical channel (Param Entry) is selected for submission to the associated physical channel (transfer controller). The association between an event queue and a physical channel can be defined in the TPCC\_QUETCMAP register. By default, TPTC0 is associated with event queue 0, and TPTC1 is associated with event queue 1. This mapping is a static decision; it does not change during DMA operation.

---

**Note:** TPTC0 and TPTC1 are not symmetrical; their numbers are just inverted, compared to the Davinci device. To improve compatibility with Davinci devices, invert the mapping of the event queue to the transfer controller, as shown below:

QUETCMAP = (QUETCMAP & ~0xFF) | 0x10;

Typically, this is used to allow submission-time preemption, so that by example:

- Event queue 0 is used for background, potentially long, not very latency-sensitive, not very critical DMA transfers.
  - Event queue 1 is used for short, latency-sensitive, or critical (for example, hardware synchronized) DMA transfers.
-

### 1.4.3.5.3 Handling Priority

In IVA2.2 local interconnect arbitration, priority of individual bus requests for a DMA transfer over other DMA- or CPU-initiated bus requests is defined by the event queue to which the event associated with the transfer is submitted. This can be configured per event queue in the TPCC\_QUEPRI[2:0] PRIQ0 and TPCC\_QUEPRI[6:4] PRIQ1 bit fields. By default, event queues 0 and 1 have the same priority (highest possible priority is 0x0).

CPU bus-requests priority is defined in the IDMA.MDMAARBE[18:16] PRI bit field. By default, the CPU has the lowest possible priority (0x7).

Typically, this is used to allow transfer-time preemption, so that, for example, bus requests associated with event queue 1 are served ahead of event queue 1 or CPU requests.

Example:

- // DMA#0->0x7 (lowest), DMA#1->0x0 (highest), CPU->0x4 (mid)
- QUEPRI = (QUEPRI & ~0xFF) | 0x07;
- MDMAARBE = (QUEPRI & ~(0xF16)) | 0x4 16;

### 1.4.3.5.4 Aged Priority

To prevent having a DMA request stalled for a very long time, the IVA2.2 implements an aged priority scheme (also referred to as an inversion priority scheme) on the DMA ports to change the priority defined in the TPCC\_QUEPRI register. This is done by regularly decreasing the priority level (increasing priority in arbitration) of a stalled request. The interval between two consecutive updates of the priority level is defined in the SYSC\_LICFG1 register. By default, the aged priority scheme is disabled (SYSC\_LICFG1=0x0), and arbitration priority is dictated by programmed values in QUEPRI and MDMAARBE.

### 1.4.3.5.5 Optimizing 2D Transfers

IVA2.2 EDMA can be configured so that DMA 2D transfers are optimized, allowing for large bursts to be generated to the SDRAM. This optimization has no effect on transfers issued as 1D transfers to the physical channels. This is recommended to enable that feature when the sources or destinations of the 2D transfers are the VRFB (SDRAM tiling structure).

To fully benefit from the optimization and disable MMU page-crossing checks:

- Large MMU page(s) are defined for the VRFB view(s) (typically 16MB super-section).
- The user software ensures that a 2D transfer does not span MMU large pages.

With the preceding conditions, use the following settings to use the IVA2.2 2D burst optimization:

- IVA\_SYSC.SYSC\_LICFG0.DMA2DOPTEN = 1
- IVA\_SYSC.SYSC\_LICFG0.PAGEXINGEN = 1

---

**Note:** The user software must ensure that a 2D transfer never spans MMU page boundaries. The reason for IVA\_SYSC.SYSC\_LICFG0.PAGEXINGEN = 1 is to remove the hardware check mechanism of 2D bursts crossing MMU pages. A 2D burst that spans these boundaries can lead to undefined behavior. PAGEXINGEN = 0 prevents such situations through hardware.

---

### 1.4.3.6 Starting the Transfer

Before starting the transfer, a trigger event must be associated with the logical channel. Three modes trigger a DMA transfer:

- Manual trigger (software-synchronized transfers)
- Hardware trigger (hardware-synchronized transfers)
- Automatic trigger (automatic on-submission transfer start)

### 1.4.3.6.1 Assigning a Logical Channel to a Trigger Event

The 64 DMA channels and the 8 QDMA channels can be flexibly mapped to any of the 128 available PaRAM entries (see [Figure 1-13](#)).

Any of the 64 DMA channels can be mapped to any of the 128 PaRAM entries through DMA channel-mapping registers TPCC\_DCHMAPi (i = 0 to 63).

Any of the 8 QDMA channels can be mapped to any of the 128 PaRAM entries through QDMA channel-mapping registers TPCC\_QCHMAPj (j = 0 to 7).

### 1.4.3.6.2 Manual Trigger (Software-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 63) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers TPCC\_DCHMAPi (i = 0 to 63). Then, the user can manually start the transfer (one logical channel or a chained list of logical channels) by writing 1 to the bit in the TPCC\_ESR or TPCC\_ESRH register associated with the trigger event of the logical channel (or the first logical channel in the chained list).

---

**Note:** The event does not need to be enabled in the TPCC\_EER register to be manually triggered.

---

Example:

```
/* -----
    */

/*To manually start defined logical channel #0x3, uses event
   #20 */

/* -----
    */

DCHMAP[20] = (DCHMAP[20] & ~(0x1FF<<5)) |
              0x3<<5;

ESR = 1 << 20;
```

### 1.4.3.6.3 Hardware Trigger (Hardware-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 19) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers TPCC\_DCHMAPi (i = 0 to 19). The user can allow this logical channel to be triggered by an associated hardware DMA request by writing 1 in the associated bit of the EER register. The mapping of a hardware DMA request to DMA events is fixed. The mapping of DMA requests to device peripheral sources is listed in [Table 1-2](#).

Example:

```
/* -----
    */

/* Associate defined logical channel #0x5 to
   UART3_DMA_TX*/

/* UART3_DMA_TX is DMA request #10 and associated to evt #10
    */

/* -----
    */

DCHMAP[10] = (DCHMAP[10] & ~(0x1FF<<5)) | 0x5<<5;
```

### 1.4.3.6.4 Automatic Trigger (QDMA)

The user can specify a trigger word from among any of the eight 32-bit words of the logical channel context (PaRAM entry) for QDMA. Writing to the trigger word triggers the channel controller of QDMA to issue a transfer request. The trigger word field of the QDMA channel mapping register TPCC\_QCHMAPj (where j = {0 to 3}) defines the trigger word for a particular QDMA channel, as shown in [Figure 1-13](#).

This flexibility enables the CPU to selectively modify only the PaRAM entry that requires modification, and thereby trigger the transfer. For example, after a transfer, if only count must change, QCHMAP can be configured so that count is the trigger word, and a write to it automatically triggers the transfer.

Example:

```
/* -----
    */
/* Associate defined logical channel #0x5 to QDMA #1
    */
/* -----
    */

QCHMAP[1] = (QCHMAP[1] & ~(0x1FF<<5)) | 0x5<<5;
/* -----
    */
/* Define DST parameter (0x3) to be trigger word of LCH
    */
/* -----
    */

QCHMAP[1] = (QCHMAP[1] & ~(0x7<<2)) | 0x3<<2;
```

In addition, the IDMA can be used to offload the CPU of the DMA configuration. See [Section 1.4.3.6.5, Offloaded Configuration \(Using IDMA\)](#).

#### 1.4.3.6.5 Offloaded Configuration (Using IDMA)

The IVA2.2 allows quick programming of DMA transfers by offloading the CPU of most of the DMA transfer issue time. To do so, the user typically maintains a copy of the logical channel contexts (PaRAM entries) in L1D SRAM. A CPU update of a logical channel context is very fast in L1D SRAM. After completing a logical channel context update, the CPU can page the context from L1D to DMA PaRAM entries using another simple DMA, internal-to-C64x + Megamodule (IDMA). For example:

```
disable_interrupts();
while(IDMA0_STATUS & 0x3);// previous IDMA completion/*
-----
    */
/* Update of logical channels definition table in L1D
    */
/* -----
    */

LCTable->OPT = opt;
LCTable->SRC = src;
LCTable->ACNT = num_bytes;
LCTable->BCNT = num_arrays;
LCTable->DST = dst;
LCTable->DSTBIDX = dbidx;
LCTable->SRCBIDX = sbidx;
LCTable->LINK = 0xFFFF;
LCTable->BCNTRLD = bcntrld;
LCTable->DSTCIDX = dcidx;
LCTable->SRCCIDX = scidx;
LCTable->CCNT = num_frames;
/* -----
    */
```

```

/* initiate IDMA transfer */
/* -----
   */

IDMA0_SOURCE = &LCTable[0];
IDMA0_DEST = &PaRAM[0];
IDMA0_MASK = 0xFFFFFFF0;
IDMA0_COUNT = 0x0;
enable_interrupts();

```

#### 1.4.3.6.6 Direct Configuration to Transfer Channel (Not Recommended)

The registers of the physical channels are memory-mapped, primarily to enable, clear, and read status for error interrupts generated by the physical channel. For more information, see [Section 1.4.8, Error Identification Process](#).

It is possible to write directly to other control registers of the physical channels and issue a transfer; however, this is not recommended and therefore is not described here.

---

**Note:** This can work safely only if the DMA controller is not used.

---

#### 1.4.3.6.7 DMA Completion Mode

The IVA2.2 EDMA defines when a DMA transfer is complete:

- Early completion: All associated transfers were submitted to the physical channel. Early completion does not ensure that transfer is complete in end memory.
  - PARAM[LCHi].OPT.TCCMODE = 1
- True completion: All associated transfers were submitted to the physical channel, and all those transfers are complete, from the physical channel standpoint. True completion ensures that transfer is complete in end memory.
  - SYSC.SYSC\_LICFG0.DMATRUECOMPEN = 1; // is statically set.
  - PARAM[LCHi].OPT.TCCMODE = 0

---

**Note:** TCCMODE = 0 does not ensure that transfer is complete in end memory if DMATRUECOMPEN = 0.

---

By default, DMATRUECOMPEN = 0. This is recommended to statically set DMATRUECOMPEN.

True completion is typically used when the IVA2.2 DMA is the producer of a buffer shared with another master processor or a DMA (consumer). A completion message is sent to the consumer only after the DMA transfer is complete.

Completion mode affects timing for the following actions:

- IPR/IPRH bit update (for polling scheme)
- Interrupt generation (for interrupt scheme)
- CER/CERH bit update (for chaining)

#### 1.4.3.6.8 Partial Versus Total Completion

DMA can be programmed so that IPR bit update and interrupt generation occur:

- After each submission to the physical channel is complete
- After the last submission to the physical channel is complete

##### Partial completion interrupt

After the submitted section (see [Section 1.4.3.4.2, Controlling Submission Granularity](#)) of a logical channel is complete, a programmable completion code is returned. If a partial completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after each LCHi submission to a physical channel is complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.ITCINTEN = 1

#### **Total completion interrupt**

After all submitted parts of a logical channel are complete, a programmable completion code is returned. If a total completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is to be set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after all LCHi submissions to a physical channel are complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.TCINTEN = 1
  - By polling
  - By interrupt

#### **1.4.3.6.9 Tracking DMA Completion**

There are two ways to track DMA completion:

- Polling the completion register when the estimated completion time has elapsed
- Enabling completion interrupts

##### **Polling example (total completion)**

- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does not contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 0<<myTCC
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)
- // poll IPR bit
- while( !(IPR & (1<<myTCC)) ); // polls for completion

##### **Interrupt example (total completion)**

- disable\_interrupts()
- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 1<<myTCC
- INTMUX[0] = (INTMUX[0] & ~(0x7F)) | 0x1D; // map CPU it #4
- CPU.IER = (CPU.IER & (1<<4)) | 1<<4; // unmask CPU it #4
- enable\_interrupts()
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)

- // this code is interrupted when DMA completes

#### 1.4.3.6.10 DMA Interrupt Service Routine

The channel controller does not generate a new interrupt signal for new pending interrupts if the user did not clear previous pending interrupts. There are two options for constructing an ISR for DMA. The first is to poll all the bits during execution of the ISR, and to clear all enabled bits in an interrupt-pending register by writing to the interrupt-pending clear (ICR/ICRH) register before exiting any ISR. Pseudo-code for this option follows:

1. Enter ISR.
2. Read TPCC\_IPR.
3. For the condition set in TPCC\_IPR,
  - a. Perform operation as needed.
  - b. Clear bit for serviced INT.
4. Read IPR.
  - a. If TPCC\_IPR = 0, exit ISR.
  - b. If TPCC\_IPR = 1, go to Step 3.

The second option is to service the ISR and then, before exiting the ISR, to write to the EVAL bit of the IEVAL register. This forces the EDMA channel controller to generate a new interrupt signal if there are still pending interrupts in the interrupt-pending register (IPR/IPRH). Pseudo-code for this ISR option follows:

1. Enter ISR.
2. Read TPCC\_IPR.
3. For the condition set in TPCC\_IPR,
  - a. Perform operation as needed.
  - b. Clear bit for serviced INT.
4. Read IPR.
  - a. If TPCC\_IPR=0, exit ISR.
  - b. If TPCC\_IPR=1, set the TPCC\_IEVAL.EVAL bit to force triggering a new interrupt.

#### 1.4.3.6.11 Benchmarking

The DMA channel controller monitors the number of event entries in an event queue to determine whether they exceed the user-programmed threshold. The queue threshold for each event queue can be programmed in the TPCC\_QWMTHRA and TPCC\_QWMTHRB registers. When the number of event entries in an event queue exceeds the user-programmed threshold, a queue threshold error occurs. This error is captured in the THRXCD field of event-queue status register TPCC\_QSTATI (i = 0 or 1) and in the QTHRXCDn field in the TPCC\_CCERR register.

#### 1.4.3.6.12 Kelvin DMA Compatibility Mode

Any channel can be configured to keep compatibility with Kelvin DMA settings. To achieve this, the user must set the TPCC\_OPTm[19] WIMODE register bit. It is recommended to always clear this bit, except when reusing existing Kelvin code.

- PARAM[LCH#].OPT.WIMODE = 0

---

**Note:** If reusing existing Kelvin code, see the *EDMA Migration Guide for DM420*.

---

## 1.4.4 IVA2.2 Extended Function Interface

This section describes the extended function interface (EFI) signals, timing, and associated instructions. The EFI runs at the CPU clock that allows the transfer of data between the CPU register file and registers at the CPU boundary that are attached to devices outside the CPU. The C64x CPU does not support an EFI. This section applies only to the C64x+ CPU. For information about other C64x+ instructions, see the *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* (TI literature number SPRU732).

### 1.4.4.1 Overview

The EFI provides hardware support for data and command transfers to registers outside the CPU in multi-CPU devices.

### 1.4.4.2 C64x+ EFI Instructions

The following instruction can be used to transfer commands by using the EFI:

- EFCMD: Send 10-bit command code

The following instructions can be used to receive data by using the EFI:

- EFRW: Receive word
- EFRDW: Receive double word

The following instructions can be used to transfer data by using the EFI:

- EFSW: Send word
- EFSDW: Send double word

#### 1.4.4.2.1 EFCMD - Send Command to EFI

**Syntax:** EFCMD (.unit) ucst10  
.unit = .S1, .S2, .M1, .M2

**Compatibility:** C64x+ CPU only

**Opcode:** .S Unit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0											0	1	1	0	1	0	0	0	0	0	1	1	1	1	0	0	s	p

**Opcode map field used ...**      **For operand type ...**      **Unit**

src2      ucst5      .S1,.S2

dst      ucst5

**Opcode:** .M Unit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0											1	1	0	1	1	0	0	0	0	0	1	1	1	1	0	0	s	p

**Opcode map field used ...**      **For operand type ...**      **Unit**

src2      ucst5      .M1,.M2

dst      ucst5

<b>Description:</b>	A 10-bit data value is sent to the EFI. The five most-significant bits (MSBs) of the 10-bit value are taken from dst; the five least-significant bits (LSBs) are taken from src2. There is an A-side EFI and a B-side EFI. The side used is determined by the S unit that is selected.
	This instruction executes unconditionally; that is, it cannot be predicated.
<b>Execution:</b>	The EFCMD instruction does not use any data path resources. It is available for scheduling purposes on the S or M units. Only one EFCMD instruction can be scheduled per side; the S or M slot on a side can be used, but not both in the same execute packet. If used in an SPLOOP body, the EFCMD instruction occupies an execution slot corresponding to the unit specified.
	The 10-bit command is output at the CPU boundary in E2. The ready signal is not sampled in conjunction with the EFCMD instruction.
<b>Instruction type:</b>	if(.S1)
	ucst10 -> A_EFI_Cmd[9:0]
<b>Delay slots:</b>	else if(.S2)
	ucst10 -> B_EFI_Cmd[9:0]
<b>Execution:</b>	else if(.M1)
	ucst10 -> A_EFI_Cmd[9:0]
<b>Instruction type:</b>	else if(.M2)
	ucst10 -> B_EFI_Cmd[9:0]
<b>Delay slots:</b>	Single-cycle
	0

#### 1.4.4.2.2 EFRDW - Receive Double Word From EFI

<b>Syntax:</b>	EFRDW (.unit) dst_o:dst_e
<b>Compatibility:</b>	.unit = .S1, .S2
<b>Opcode:</b>	C64x+ CPU only

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0					dst	0	0	0	0	0	0	1	1	1	1	0	1	1	1	1	0	0	1	0	0	0	s	p

<b>Opcode map field used ...</b>	<b>For operand type ...</b>	<b>Unit</b>
dst	dint	.S1,.S2

<b>Description:</b>	A 64-bit data value is read from the EFI and is written to the register pair dst_o:dst_e. There is an A-side EFI and a B-side EFI. The side used is determined by the S unit that is selected. There is no cross-path capability: A-side receives must go to an A-file register pair, and B-side receives must go to a B-file register pair. This instruction executes unconditionally; that is, it can not be predicated.
	The ready signal is sampled in the DS phase of the EFRDW instruction and will cause the CPU to stall before the EFRDW instruction reaches E1 if the data to be read has not yet been registered in the CPU.
<b>Execution:</b>	if(.S1)
	A_EFI_Din[63:0] -> dst_o:dst_e (A1:A0 – A31:A30)
<b>Instruction type:</b>	else // .2
	B_EFI_Din[63:0] -> dst_o:dst_e (B1:B0 – B31:B30)
<b>Delay slots:</b>	Single-cycle
	0
<b>See also:</b>	EFRW

#### 1.4.4.2.3 EFRW - Receive Word From EFI

**Syntax:** EFRW (.unit) dst  
.unit = .S1, .S2

**Compatibility:** C64x+ CPU only

**Opcode:**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0				dst		0	0	0	0	0	0	1	1	1	0	0	1	1	1	1	0	0	1	0	0	0	s	p

**Opcode map field used ...**      **For operand type ...**      **Unit**

dst      int      .S1,.S2

**Description:**

A 32-bit data value is read from the EFI and is written to dst. There is an A-side EFI and a B-side EFI. The side used is determined by the S unit that is selected. There is no cross-path capability: A-side receives must go to an A-file register pair, and B-side receives must go to a B-file register pair. This instruction executes unconditionally; that is, it can not be predicated. The ready signal is sampled in the DS phase of the EFRW instruction and will cause the CPU to stall before the EFRDW instruction reaches E1 if the data to be read has not yet been registered in the CPU.

if(.S1)

**Execution:**

A\_EFI\_Din[31:0] -> dst (A0 – A31)

else // .2

B\_EFI\_Din[31:0] -> dst (B0 – B31)

**Instruction type:**

Single-cycle

**Delay slots:**

0

**See also:**

EFRDW

#### 1.4.4.2.4 EFSDW - Send Double Word to EFI

**Syntax:** EFSDW (.unit) src1, src2, dst  
.unit = .L1, .L2

**Compatibility:** C64x+ CPU only

**Opcode:**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
creg		z		dst				src2				src1				x		0	1	1	1	0	1	0	1	1	0	s	p		

**Opcode map field used ...**      **For operand type ...**      **Unit**

src1      int      .L1, .L2

src2      xint

dst      ucst5

**Description:**

The registers src1 and src2 are read from the register file and combined to form a 64-bit value that is sent to the EFI with a 5-bit constant taken from dst. The src2 register provides the 32 LSBs, and the src1 register provides the 32 MSBs. There is an A-side EFI and a B-side EFI. The side used is determined by the L unit that is selected.

The data and constant are output at the CPU boundary in E2. The EFI ready signal is sampled in E2 of the EFSDW instruction and will cause the CPU to stall if the signal indicates the buffering external to the CPU is full.

```

                                if(cond)
                                  if(.L1)
                                    src1:src2 -> A_EFI_Dout[63:0]
                                    ucst5 -> A_EFI_Scmd[4:0]
Execution:                      else // .L2
                                  src1:src2 -> B_EFI_Dout[63:0]
                                  ucst5 -> B_EFI_Scmd[4:0]
                                  else
                                    nop
Instruction type:                Single-cycle
Delay slots:                    0
See also:                       EFSW

```

#### 1.4.4.2.5 EFSW - Send Word to EFI

**Syntax:** EFSW (.unit) src1, dst  
.unit = .L1, .L2

**Compatibility:** C64x+ CPU only

**Opcode:**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
creg			z				dst				src2		0	1		1	1	1	x	0	0	1	1	0	1	0	1	1	0	s	p

Opcode map field used ...	For operand type ...	Unit
src2	xint	.L1, .L2
dst	ucst5	

**Description:** The src2 register is read from the register file and sent to the EFI along with a 5-bit constant taken from dst. There is an A-side EFI and a B-side EFI. The side used is determined by the L unit that is selected. The data and constant are output at the CPU boundary in E2. The EFI ready signal is sampled in E2 of the EFSW instruction and will cause the CPU to stall if the signal indicates the buffering external to the CPU is full.

```

                                if(cond)
                                  if(.L1)
                                    src2 -> A_EFI_Dout[31:0]
                                    ucst5 -> A_EFI_Scmd[4:0]
Execution:                      else // .L2
                                  src2 -> B_EFI_Dout[31:0]
                                  ucst5 -> B_EFI_Scmd[4:0]
                                  else
                                    nop
Instruction type:                Single-cycle
Delay slots:                    0
See also:                       EFSDW

```

#### 1.4.4.3 C64x+ EFI Use in IVA2.2

The following programming model describes how to write and read a register using the EFI. In the context of IVA2.2, only the EFSW, EFRW, and EFSDW instructions are used.

#### 1.4.4.3.1 Read Registers Using the EFI Programming Model

To read a 32-bit value in a video accelerator register using the EFI, the following sequence must be used:

```
EFSW address_32b, opcode_5b
NOP N
EFRW cpu_reg
```

With:

- address\_32b is the video accelerator address of the register from which the value must be read.
- opcode\_5b is used to code the read operation: 0x02.
- N is the number of cycles to wait until data is written in the EFI FIFO. In the context of IVA2.2 N = 0x22.
- Cpu\_reg is the 32-bit CPU register where the read value is stored.

---

**Note:** To avoid handling specific cases of successive read requests, interrupts are disabled between the time the EFSW is issued and the data is retrieved in the DSP register.

---

---

**Note:** When it is necessary to read a large number of registers, the two macros that correspond to the two instructions given previously can be used to allow issuing a read request while reading data:

```
EFSW address_32b, opcode_5b: IME_SendReadReq(unsigned ime_addr_reg)
```

```
EFRW cpu_reg: IME_ReceiveData()
```

---

In that case there is no need to insert a NOPs instruction between the two EFI commands. Read latency is under CPU control.

#### 1.4.4.3.2 Write Registers Using the EFI Programming Model

To write a 32 bit-value in a video accelerator register using the EFI, the following instruction must be used:

```
EFSDW value_32b, address_32b, opcode_5b
```

With:

- The value\_32b register contains the 32-bit word to write.
- address\_32b is the video accelerator address of the register in which value must be written.
- opcode\_5b is used to code the write operation: 0x01.

---

**Note:** The address is stored in the even 32-bit register of the 64-bit register pair, while value\_32b is stored in the odd register (that is, the MSB part).

---

### 1.4.5 Interrupt Management

#### 1.4.5.1 Interrupt Flow in IVA2.2 Subsystem

The C64x + Megamodule interrupt controller (IC) detects, combines, and routes up to 128 system events (internal and external) to the 12 DSP CPU interrupt lines. For more information about interrupt mapping of the IVA2.2 subsystem (internal and external interrupts), see [Table 1-3](#).

In addition to performing handshaking for chip-level wake-up sequencing for waking from static power-down, the C64x + Megamodule WUGEN module internally routes the interrupt request to the IC module. This occurs because the WUGEN module is the only C64x + Megamodule module in the CORE power domain to enable the powered-off DSP subsystem to be awakened after the DSP receives an interrupt from any device peripherals.

[Figure 1-26](#) shows the IVA2.2 subsystem interrupt flow with the main WUGEN and IC registers used for event generation.

### 1.4.5.2 Event Combined Programming Sequence

In addition to generating a combined interrupt based on programmable event combinations, the event combiner provides a masked view of the event flag registers. By reading the masked event flag (IVA\_IC.MEVTFLAGi where i = {0 to 3}) registers, the DSP CPU sees only the event flags pertaining to the corresponding combined event (EVTx with x = {0, 1, 2, 3}).

When servicing a combined interrupt, perform the following steps:

1. Read the IVA\_IC.MEVTFLAGi register corresponding to the combined event EVTx (where i = {0 to 3}).
2. Check the pending events.
3. Write the value of the IVA\_IC.MEVTFLAGi register into the IVA\_IC.EVTCLRi register (where i = {0 to 3}).
4. Service the received interrupts.
5. Repeat steps 1 through 4 until IVA\_IC.MEVTFLAGi = 0x0 (where i = {0 to 3}).

This clears only those events combined on EVTx. Any events masked in the IVA\_IC.EVTMASKi register (where i = {0 to 3}) do not need to be cleared if set in the IVA\_IC.EVTFLAGi register (where i = {0 to 3}) (they can generate an exception or are used as event outputs).

Before returning, the DSP CPU should repeat steps 1 through 4 until no pending events are found. This ensures that any events received during the ISR are captured. If an event EVTx is received at the same time that its flag is being cleared in the IVA\_IC.EVTCLRi register (where i = {0 to 3}), it does not clear. Repeating steps 1 through 4 ensures that no events are missed.

### 1.4.5.3 Event <-> Interrupt Mapping Programming Sequence

The INTC allows programming independently which of the 128 inputs events is mapped to each DSP CPU interrupt by writing the event number in the bit field corresponding to the CPU interrupt in the IC.INTMUXi registers (where i = {1 to 3}).

Example:

```
/* -----
    */

/*evtTable has the 12 evt <-> CPU interrupt
   mapping */

/* -----
    */

evtTable[0] = 55; // Mailbox event highest priority
evtTable[1] = 61; // McBSP1TX event
[...]
evtTable[11] = 29; // EDMA3 gbl completion event lowest
                priority
for(I=0; i<12; I++) { // for each CPU maskeable
    interrupt
    INTMUX(I >> 2 + 1) |= (evtTable[i] & 0x7F) <<
        ((I & 0x3) << 3);
}
```

### 1.4.5.4 Interrupt Exception Programming Sequence

The INTC can generate a system event (INTERR) that is internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is dropped (that is, when a DSP CPU interrupt is received while the interrupt flag is already set in the DSP CPU).

This can inform the user of possible problems in the software code, such as whether interrupts were disabled for an extended period of time, or whether pipelined (noninterruptible) code sections were too long.

---

**Note:** Because the interrupt drop detection logic is in the CPU, only interrupts sourced from a single system event can be detected. The dropping of individual combined events is not possible, although dropping the output of an event combiner is possible. Only the first dropped interrupt detected is reported by the INTERR event.

---

The IVA\_IC.INTXSTAT register holds the ID of the CPU interrupt and the system event number of the dropped event. By setting the IVA\_IC.INTXCLR[0] CLEAR bit to 1, the software user resets the IVA\_IC.INTXSTAT register to 0.

When servicing the interrupt exception, the CPU performs three steps:

1. Reads the IVA\_IC.INTXSTAT register
2. Checks the error condition
3. Clears the error through the IVA\_IC.INTXCLR register

The dropped events that generate the INTERR event (EVT96) can be qualified by a mask register. CPU interrupts that are to be ignored by the drop detection hardware can be masked in the IVA\_IC.INTDMASK register.

#### 1.4.5.5 Interrupt Controller Basic Programming Model for Power Down of IVA2.2 Subsystem

When going to a low-power state not involving IVA2.2 logic power off, there are no special software settings to perform. In particular, the noncombined interrupts can be used without any specific handling for that power transition. To run the procedure for a correct transition to power-down state not involving logic-off, the user must perform the following sequence:

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts, and are unmasked in combined event registers (if combined events are used).
2. Clear associated bits in the WUGEN\_MEVT0 and WUGEN\_MEVT1 register to unmask wake-up interrupts.

---

**Note:** Software must not unmask in the WUGEN module an event that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the IVA2.2 subsystem exits the power-down state but does not wake up.

---

The user must program the following procedure when transitioning to the (logic) power-off state (OFF state for device):

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts, and are unmasked in combined event registers (if combined events are used).
2. Clear correct bits in the WUGEN\_MEVT0 and WUGEN\_MEVT1 registers to unmask wake-up interrupts.
3. Save necessary context (all except interrupt-related registers).

---

**Note:** Steps 3 through 5 are automatic, but interruptible. If a wake-up interrupt occurs at this stage, the transition to power down is canceled and the next transition restarts from the beginning. Software tip: A software variable (semaphore) can be set in Step 3, modified in all calls of the wake-up interrupt ISR routine, and checked before executing the IDLE instruction in Step 5. For a complete description of the DSP CPU ISR register, see the C64x+ documentation.

---

4. Save the interrupt configuration in:
  - a. IVA\_IC.INTMUXi register (where i = {1 to 3})
  - b. IVA\_IC.EVTMASKi register (optional, where i = {0 to 3})
  - c. IVA\_IC.INTDMASK register (optional)
  - d. DSP CPU IER register. See the C64x+ documentation for IER register description.
5. Execute the DSP IDLE instruction.

---

**Note:** Software must not unmask in the WUGEN module an event that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the IVA2.2 subsystem exits the power-down state but does not wake up.

---

#### 1.4.5.6 Interrupt Controller Basic Programming Model for Power On of IVA2.2 Subsystem

noncombined events can be lost after power on wakeup of the C64x + Megamodule module. To avoid this, one solution is to replay the DSP CPU interrupt after restoring the interrupt selector and event combiner context.

- Programming model at boot time

There is no specific software setting needed to use combined/noncombined events during normal operation. However, at boot time, the event can be captured in the event-combiner event flag and not propagated to DSP. For this purpose, the following sequence must be performed:

1. The IVA2.2 logic ensures that interrupts are only presented to C64x + Megamodule after:
  - a. The C64x + Megamodule module has its clock.
  - b. The C64x + Megamodule module is correctly reset.

---

**Note:** Steps a and b ensure that the C64x + Megamodule module cannot miss a dropped event.

---

2. From the time the pre-idle sequence is started to the time when the IVA2.2 context is fully restored and operational after wakeup, it is assumed that only external (from device peripherals) interrupts can occur. C64x + Megamodule internal interrupts can result only from an application software side-effect; the application is stopped when entering the pre-idle sequence and is restarted only after IVA2.2 context is fully restored and operational (with special attention to memory protection). EDMA interrupts are inactive at this stage, as the EDMA module is completely reset after power up, and a software action is required to make the EDMA interrupts active again.
3. All device peripheral interrupts are level and are kept asserted until the software acknowledges the interrupt by writing 1 to the interrupt status register (DSP CPU ISR) bit corresponding to the enabled asserted event(s). The device peripheral must keep an event flag to track missed interrupts. For a complete description of the DSP CPU ISR register, see the C64x+ documentation.
4. There is no specific requirement to configure or restore interrupt mapping, except having the interrupts globally disabled during the sequence:
  - a. Set the DSP CPU TSR[0] or CSR[0] GIE bit to 0 to disable all interrupts except the reset interrupt and NMI (nonmaskable interrupt). The GIE bit is the same physical bit in the TSR and CSR registers. For a complete description of these registers, see the C64x + documentation.
  - b. Remap interrupts by configuring the IVA\_IC.INTMUX<sub>i</sub> registers (where i = {1 to 3}).
  - c. Set the DSP CPU TSR[0] or CSR[0] GIE bit to 1 to enable all DSP CPU interrupts.

The DSP CPU software recognizes which degree of power state the C64x reaches when executing the IDLE instruction, because the PRCM module is under C64x software control. Therefore, the DSP CPU software can correctly skip some unnecessary parts of the pre-idle routines.

- State after reset for DSP CPU and IVA2.2 IC registers:
  - The DSP CPU IER register value is 0x0.
  - The DSP CPU IFR register value is 0x0 because the interrupt selector default mapping is routing only emulation and unmapped events.
  - The IVA\_IC.INTMUX<sub>i</sub> registers (where i = {1 to 3}): The default mapping is to route EVT<sub>x</sub> (with x = {0 to 3}) on INT<sub>y</sub> (with y = {4 .. 15}), that is, emulation and nonmapped events.
  - The IVA\_IC.EVTMASK<sub>i</sub> registers (where i = {0 to 3}) value is 0x0 (all events are unmasked). These registers values are don't care values because of the default interrupt selector mapping (where IVA\_IC.INTMUX<sub>i</sub> registers where i = {1 to 3}).
  - The IVA\_IC.EVTFLAG<sub>i</sub> registers (where i = {0, 1, 2, 3}): These registers log the possible wake-up interrupt(s) (if more than one). At this stage, a new wake-up interrupt from device peripherals cannot be missed, because interrupts are level in the device, waiting for a software acknowledge (the user must clear the interrupt in the module to de-assert the interrupt line).

For a complete description of the DSP CPU IER and IFR registers, see the C64x+ documentation.

- State after reset for WUGEN registers: two cases depending on the reset type:
  - In case of cold power-on reset (the CORE power domain was in OFF state), the IVA\_WUGEN.WUGEN\_MEVT0 register value is 0xFFFFFFFF and the IVA\_WUGEN.WUGEN\_MEVT1 register value is 0xFFFF, meaning that all interrupts are masked.
  - In case of warm power-on reset (the CORE power domain was in ACTIVE state), the WUGEN\_MEVT0 and WUGEN\_MEVT1 registers value is the previous programmed one, enabling only wake-up interrupts.
- Programming model for a correct warm-reset:

The software user must replay the noncombined events required for wakeup (if any):

1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
2. Restore the interrupt selector configuration:
  - a. IVA\_IC.INTMUXi register (where i = {1 to 3})
  - b. IVA\_IC.EVTMASKi register (optional, where i = {0 to 3})
  - c. IVA\_IC.INTDMASK register (optional)
3. Replay the noncombined event captured in IVA\_IC.EVTFLAGi (where i = {0 to 3}):
 

For each DSP CPU interrupt I = (4 to 15)

```
{
a. Grab mapped event by setting the IVA_IC.INTMUXi INTSELi[6:0] field (where i = {1 to 3}).
b. Check if the event is combined (EVT0...3) or not combined (EVT4...127).
c. If combined, exit the loop and go to next loop iteration.
d. If noncombined:
    i. Check whether the event is pending in the IVA_IC.EVTFLAGi EFi bit (where i = {0 to 3} and y = {0 to 127}).
    ii. If not pending, exit the loop and go to the next loop iteration.
    iii. If pending, set the associated IFi bit in the DSP CPU IFR register.
}
```

---

**Note:** Software must ensure that an event is enabled only once in the C64x + Megamodule interrupt selector/combiner: If a noncombined event is mapped to an enabled DSP CPU interrupt, the associated combined event is masked in the associated IVA\_IC.EVTMASKi (where i = {0 to 3}) register (and/or the combined event is not mapped to the DSP CPU interrupt). Reciprocally, if a combined event is mapped to a DSP CPU interrupt, all the unmasked events in the associated IVA\_IC.EVTMASKi (with i = {0, 1 to 3}) register are not mapped as noncombined events to an enabled DSP CPU interrupt (through the DSP CPU IER register).

---

Software program example for Step 3:

```
/* -----
   */
/* Replays IFR bits associated to noncombined events
   */
/* Assumes interrupts globally disabled (GIE bit set to
   0)*/
/* Assumes IVA_IC.INTMUXi() and IVA_IC.EVTFLAGi() are access
   macros to C64x + Megamodule IC registers */
/* -----
   */

myIPR = IPR; // save IPR
for(I=0; i<12; I++) { // for each CPU maskable
    interrupt
    myEvt = ( INTMUX( I >> 2 + 1 ) >> ( ( I & 0x3 )
        << 3 ) ) & 0x7F;
```

```

if(myEvt >= 4) { // noncombined event
if( (EVTFLAG(myEvt >> 5) >> (myEvt & 0x1F) )
    & 0x1 ) {

myIPR |= (1<<(I+4));
}
}
}

IPR=myIPR; // update IPR register
/* -----
    */

/* Interrupts can be globally re-enabled from that
    point*/

/* -----
    */

```

4. Restore the CPU interrupt configuration by setting the DSP CPU IER register accordingly.
5. Restore the IVA2.2 context (except saved return-PC).
6. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
7. Branch to saved return-PC.

For a complete description of the DSP CPU TSR, CSR, IER, or IFR registers, see the C64x+ documentation.

- Procedure for a correct cold reset
  1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
  2. Restore the interrupt selector configuration:
    - a. IVA\_IC.INTMUXi register (where i = {1 to 3})
    - b. IVA\_IC.EVTMASKi register (optional, with i = {0 to 3})
    - c. IVA\_IC.INTDMASK register (optional)
  3. It is unnecessary to replay events, because they are masked in WUGEN\_MEVT0 and WUGEN\_MEVT1 registers (default WUGEN module configuration). This can be done to simplify the boot sequence without discriminating between cold and warm reset.
  4. Restore the CPU interrupt configuration by setting the DSP CPU IER REGISTER accordingly.
  5. Restore the WUGEN module context. This can be forced even in warm reset to simplify the boot sequence without discriminating between cold and warm reset.

---

**Note:** If Steps 3 and 5 are performed systematically, the boot code can be shared between warm and cold reset boot without programming two distinct software boot codes.

---

6. Restore the rest of the IVA2.2 subsystem context (except saved return-PC).
7. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
8. Branch to saved return-PC.

## 1.4.6 Memory Management

### 1.4.6.1 External Memory

#### 1.4.6.1.1 Cacheability

The L1P, L1D, and L2 cache sizes are all 0K byte after reset.

- The user enables the L2 cache by writing 0x2 (maximum cache is 64K bytes) to the IVA\_XMC.L2CFG register.
- However, this is not sufficient, because the region external to the IVA2.2 is configured as a noncached area after reset. The user must configure the external area to be cached by setting the IVA\_XMC.MARi[0] PC bit to 1, i referring to the index of the related 16-MB page (starting from i = 16 for the first external page at address 0x1000 0000).

The MAR settings only control the L2 and L1D cache's response to CPU data and program fetches. L1P caches the memory range regardless of the values of the MAR bits.

#### 1.4.6.1.2 Virtual Addressing

The device embeds two instances of MMU: one instance is camera MMU (also named MMU1) dedicated to the camera subsystem; the other instance is IVA2.2 MMU (also named MMU2) used by the IVA2.2 subsystem. For more information about MMU2 software settings at IVA2.2 boot, see [Section 1.4.1.2, Example of IVA2.2 Boot](#).

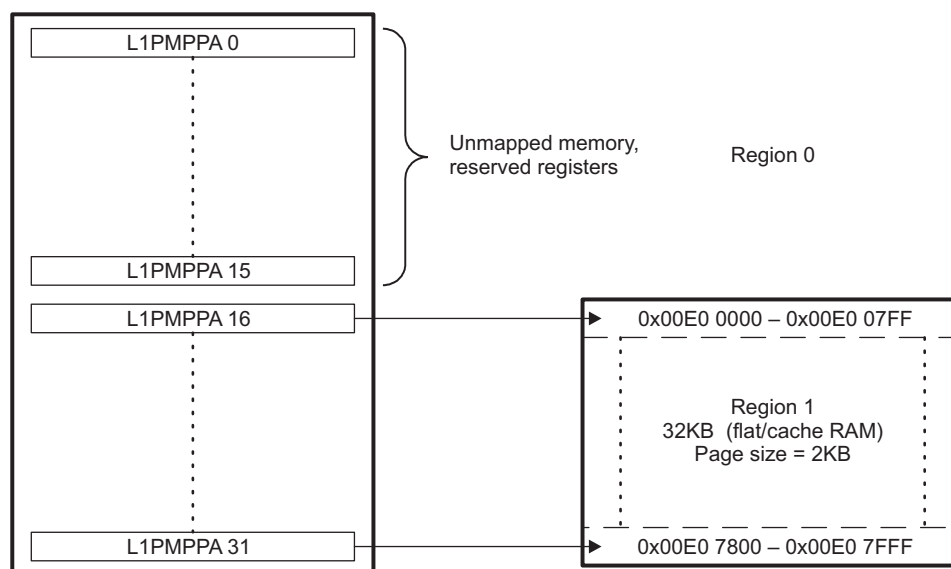

For a complete programming guide of IVA2.2 MMU, see the *Memory Management Units* chapter.

### 1.4.6.2 Internal Memory

#### 1.4.6.2.1 Memory Protection

The C64x + Megamodule memory protection divides the memory map into pages and defines a per-page permission structure. This permission structure is in the MPPA registers: IVA\_XMC.L1PMPPAk, IVA\_XMC.L1DMPPAk, IVA\_XMC.L1PMPPAk for L1P, L1D, L2 memory protection, and TPCC\_MPPAG, TPCC\_MPPAj for EDMA memory protection. [Figure 1-27](#), [Figure 1-28](#), and [Figure 1-29](#) show which register corresponds to each page permission structure.

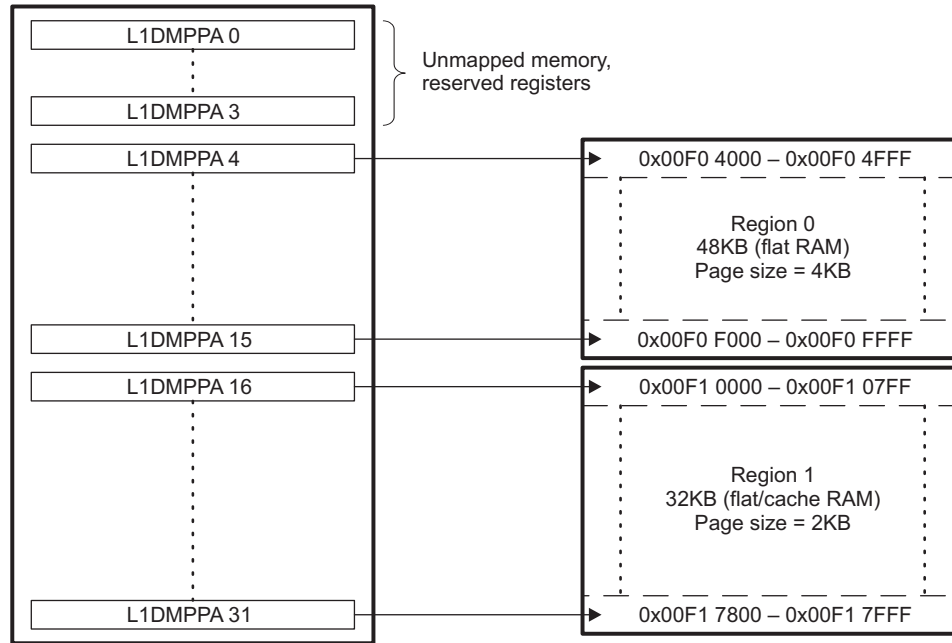

**Figure 1-27. L1P Memory Protection Registers**

iva22-042

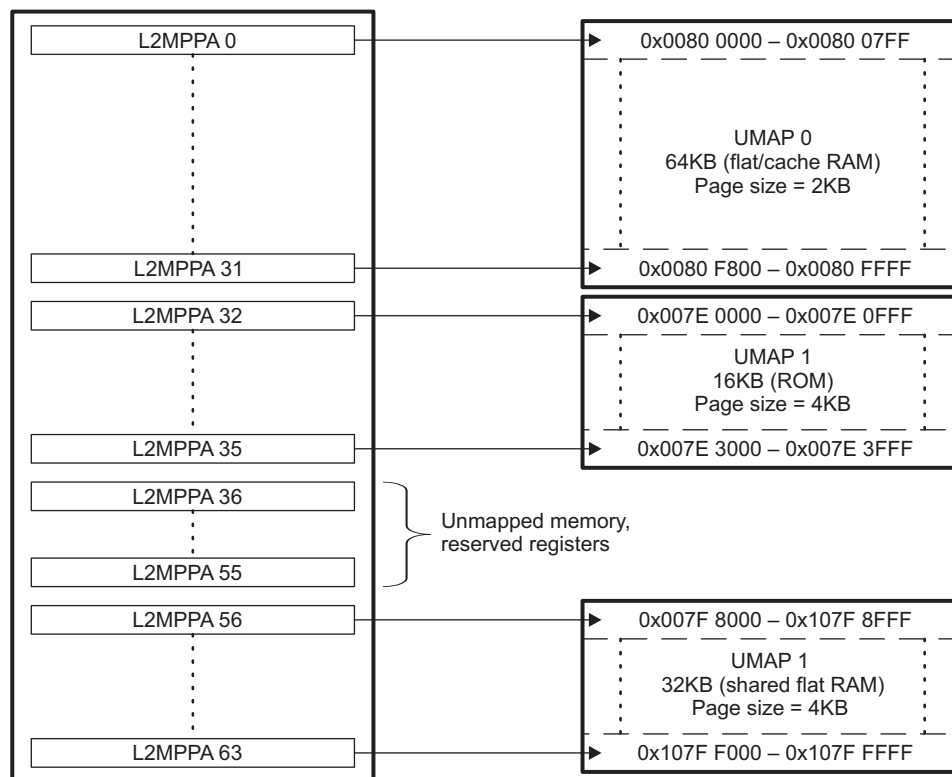

**Figure 1-28. L1D Memory Protection Registers**

iva22-043

**Figure 1-29. L2 Memory Protection Registers**

iva22-044

**Note:** When memory is used as cache, all its corresponding MPPA registers should be set to 0x0000.

Table 1-14 shows which register corresponds to each memory address for megacell internal memory.

**Table 1-14. IVA2.2 Megacell Memory Protection Page Registers**

Register Number	L1PMPPAk, Address Range	L1DMPPAk, Address Range	L2MPPAj, Address Range
0	N/A <sup>(1)</sup>	N/A	0x0080 0000 - 0x0080 07FF

<sup>(1)</sup> N/A = nonmapped memory. All corresponding registers should be considered reserved.

All these registers include three permission fields in a 16-bit permission entry in the memory protection page attribute MPPA register:

- Allowed ID field:

Each requestor on the device has an N-bit code associated where it that identifies it for privilege purposes. This code, referred to as the VBUS PrivID, accompanies all memory accesses and DMAs/IDMAs on behalf of that requestor. That is, when a requestor triggers a DMA/IDMA transfer directly, either by writing to IDMA registers or by triggering the execution of a set of EDMA parameters, the corresponding DMA engine captures the PrivID of the requestor and provides that PrivID with the transfer.

Each memory protection entry is associated with an 8-bit allowed-IDs field that indicates which requestors can access the given page. The memory protection hardware maps the PrivIDs of all possible requestors to bits in the allowed-IDs field in the memory protection entries. The allowed-IDs field discriminates among the various CPUs, non-CPU requestors, and the accesses of a given CPU to its own local memories:

- AID0 through AID5 map small-numbered VBUS PrivIDs to allowed ID bits.
- An additional allowed-ID bit, AIDX, captures accesses by higher-numbered PrivIDs.
- The LOCAL bit treats CPU accesses to its local L1s and L2 specially. Only the L1 and L2 memory controllers implement the LOCAL bit.

When set to 1, the AID bit grants access to the corresponding PrivID. When set to 0, the AID bit denies access to the corresponding requestor.

PrivID assignments for bits AID0 through AIDX apply to:

- CPU memory and IDMA memory: IVA\_XMC.L1PMPPAk[15:9] for L1P memory, IVA\_XMC.L1DMPPAk[15:9] for L1D memory, and IVA\_XMC.j[15:9] for L2 memory
- EDMA memory: TPCC\_MPPAG[15:9] and TPCC\_MPPAj[15:9] for EDMA block

The AIDX bit maps to PrivIDs that do not have dedicated AID bits associated with them. This bit refers to external mastering peripherals, especially on devices with a large number of CPUs. If a given device must discriminate among external mastering peripherals, it can assign lower-numbered PrivIDs to these peripherals.

For the EDMA module, the AIDX bit is the TPCC\_MPPAj[9] and TPCC\_MPPAj[9] EXT bits.

The LOCAL bit governs DSP CPU accesses to its own local L1 and L2 memories. It is defined in IVA\_XMC.L1PMPPAk[8] for L1P memory, in IVA\_XMC.L1DMPPAk[8] for L1D memory, and in IVA\_XMC.L2MPPAj[8] for L2 memory. It is not defined for EDMA.

With respect to the allowed ID field, the C64x + Megamodule treats all remote CPU accesses to C64x + Megamodule memories identically to DMA accesses from that remote CPU. Therefore, C64x + Megamodule uses the PrivID to consult the corresponding AID bit when considering remote accesses.

However, the DPS megacell module never compares local accesses to L1 and L2 memory against the AID bits in the allowed ID field. Instead, it consults the LOCAL bit to determine whether the CPU can access its local memory.

With this scheme, a software program can designate a page as direct CPU access only by setting the LOCAL bit to 1 and setting all other allowed IDs to 0. Conversely, a software program can designate a page as DMAs issued from this CPU only by setting its AID bit and clearing the LOCAL bit. Such a setting is limited, but it can be useful in a high-secure environment such as a secure device, or in the context of a device driver.

- Request-Type Based Permissions field:

The DPS megacell memory protection model defines three fundamental functional access types: read, write, and execute. Read and write refer to data accesses originating through the load/store units on the DSP CPU or through the DMA/IDMA engines. Execute refers to accesses associated with program fetch.

The C64x + Megamodule memory protection model allows control of read, write, and execute permissions independently for both user and supervisor mode. This results in the 6-bit permission field shown in [Table 1-15](#).

**Table 1-15. Request-Type Access Controls**

Bit Name	Description
SR	Supervisor can read
SW	Supervisor can write
SX	Supervisor can execute <sup>(1)</sup>
UR	User can read
UW	User can write
UX	User can execute <sup>(1)</sup>

<sup>(1)</sup> IVA\_XMC.L1DMPPAXX do not implement these bits.

For each bit, writing 1 permits the access type, and writing 0 denies it. For instance, setting the UX bit to 1 means that user mode can execute from the given page. The C64x + Megamodule allows specifying all six of these bits separately. For L1P, L1D, and L2 memories, and for EDMA, these bits are defined in IVA\_XMC.L1PMPPAk[5:0], IVA\_XMC.L1DMPPAk[5:0], IVA\_XMC.L2MPPAj[5:0], and TPCC\_MPPAG[5:0] and TPCC\_MPPAj[5:0], respectively.

**Note:** IVA\_XMC.L1DMPPAk do not implement the SX and UX bit, because execution is not possible from L1D memory. Therefore, these bits are reserved and should not be used in these registers.

- Other registers

The memory protection block records the address of the fault in the peripheral memory protection fault address register (MPFAR). It records the rest of the information about the fault in the peripheral memory protection fault status register (MPFSR); this register is formatted similarly to the MPPA. Software can write to the memory protection fault command register (MPFCR).

The MPFAR corresponds to the following registers: IVA\_XMC.L1PMPFAR for L1P memory, IVA\_XMC.L1DMPFAR for L1D memory, IVA\_XMC.L2MPFAR for L2 memory, IVA\_IDMA.ICFGMPFAR for IDMA, and TPCC\_MPFAR for EDMA.

The MPFSR corresponds to the following registers: IVA\_XMC.L1PMPFSR for L1P memory, IVA\_XMC.L1DMPFAR for L1D memory, IVA\_XMC.L2MPFSR for L2 memory, IVA\_IDMA.ICFGMPFSR for IDMA, and TPCC\_MPFAR for EDMA.

Using the MPFSR register, a memory protection fault can be decoded as follows by software:

- If the LOCAL status bit is set to 1, the request was a local DSP CPU request to its own memories. Otherwise (if the LOCAL status bit is set to 0), the VBUS ID of the faulting requestor is in the MPFSR[15:9] field.
- If the NS status bit is set to 1, the fault occurred in secure code. Otherwise (if the NS status bit is set to 0), it occurred in regular code.
- The value of the access type field (SR, SW, SX, UR, UW, UX) indicates the type of access that was at fault.

The MPFAR and MPFSR store information for only one fault. The hardware block holds the fault information until the software clears it by writing to MPFCR.

The user clears the recorded fault by setting the MPFCR[0] MPFCLR bit to 1. Writing 1 to this bit clears both MPFAR and MPFSR registers. The MPFAR and MPFSR read-only registers do not respond to writes. Once the user clears the fault, the hardware records the next protection violation, and signals an exception when it occurs. Writing 1 to any other bit of the MPFCR has no effect on the memory protection registers. Writing 0 to the MPFCR[0] MPFCLR bit also has no effect.

The MPFCR corresponds to the following registers: IVA\_XMC.L1PMPFCR for L1P memory, IVA\_XMC.L1DMPFAR for L1D memory, IVA\_XMC.L2MPFCR for L2 memory, IVA\_IDMA.ICFGMPFCR for IDMA, and TPCC\_MPFAR for EDMA.

- Events generated to C64x + Megamodule IC block

Internal events are generated to inform the C64x + Megamodule module for memory protection:

- CCMPINT (EVT28) is generated for a TPCC memory protection interrupt.
- SYS\_CMPA (EVT 119) is generated in case of a SYS CPU memory protection fault.
- PMC\_CMPA (EVT120) and PMC\_DMPA (EVT121) are generated in case of CPU and DMA memory protection faults, respectively, on PMC.

- DMC\_CMPA (EVT122) and DMC\_DMPA (EVT123) are generated in case of CPU and DMA memory protection faults, respectively, on DMC.
- UMC\_CMPA (EVT124) and UMC\_DMPA (EVT125) are generated in case of CPU and DMA memory protection faults, respectively, on UMC.
- PMC\_CMPA (EVT126) is generated in case of a CPU memory protection fault on EMC.

The AID of the DSP appears in the DNUM control register in the CPU. DNUM is the DSP core number register; it is used to identify which DSP subsystem accessed the shared resources. Because there is only one C64x+:

- GEM\_DNUM[7:4] always equals 0x0.
- GEM\_DNUM[3:0] equals 0x0 because C64x + Megamodule is labeled as CPU0 in the single core system.

Thus, the possible requestors are:

- C64x
- IDMA
- EDMA
- Any device L3 initiator (through the IVA2.2 slave port)

The PrivID (relative to the DNUM register) equals 0. The ID of IVA DMA accesses is always 0x0, because the IVA DMA inherits ID from C64x + Megamodule. All accesses on the IVA2 slave port to local memories are seen by C64x + Megamodule as accesses from an external (non-C64x + Megamodule) initiator.

Thus, the hard-mapped memory protection IDs are:

- AID0, used for IVA DMA
- AID1 to AID5 (not used)
- AIDX, used by the slave port (L3 initiators)
- LOCAL bit, used by DSP loads, stores, and program fetches to memory attached directly to C64x + Megamodule

#### 1.4.6.2.2 Bandwidth Management

The bandwidth management scheme can be summarized as weighted-priority-driven bandwidth allocation. Each requestor (EDMA, IDMA, CPU, etc.) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system: there is a total of nine priority levels, where priority 0 is highest and priority 8 is lowest priority. When requests for a single resource contend, access is granted to the highest priority requestor. When contention occurs for multiple successive cycles, a contention counter ensures that the lower priority requestor gets access to the resource every one out of  $n$  arbitration cycles, where  $n$  is programmable through the MAXWAIT field. For each identified requestor, a corresponding MAXWAIT field controls the maximum number of cycles that a request can be blocked.

- CPUARB registers: CPU priority and MAXWAIT programming model

The DSP CPU-initiated transfers consist of two components:

1. Program fetch transfers are issued by the CPU to the PMC, and the resulting L1P cache coherency operations (such as alloc/evict) are then issued to the UMC.
2. Data load/store transfers are issued by the CPU to the DMC, and the resulting L1D cache coherency operations (such as alloc/evict/long distance accesses) are then issued to the UMC.

Both program and data requests use the CPUARB values to define the maximum wait time (CPUARB[5:0] MAXWAIT) and priority (CPUARB[18:16] PRI). The effect of the CPUARB values is not just local to PMC or DMC. Priority/maxwait time applies to DMC/PMC cache transactions throughout the C64x + Megamodule and controls arbitration at each relevant sub-block within C64x + Megamodule. The priority (PRI) and MAXWAIT field is programmed locally in the UMC, DMC, and EMC blocks, through the IVA\_UMC.CPUARBU, IVA\_DMC.CPUARBD, and IVA\_IDMA.CPUARBE PRI and MAXWAIT fields, respectively.

The default value of the CPUARB[18:16] PRI field is set so that CPU transactions are second to highest in the system. This should be a relatively typical value used in most systems, which results in the DSP CPU being granted highest priority most of the time, but a McBSP-type peripheral (typically programmed as the highest priority transfer for sDMA requests) can interrupt the DSP CPU transfers on a nearly immediate basis.

---

**Note:** CPU priority is software-programmable, but it is considered static (1-time-programmable) for bandwidth management. That is, during normal operation, all DSP CPU transactions are of the same priority. There is no concept of priority inheritance for CPU-initiated transfers as a result of CPU transfer A set at priority X and CPU transfer B set at priority Y. Because CPUARB must be programmed by the CPU, and is therefore a run-time program, the effect of the new CPUARB value must take effect for future CPU transfers.

---

- UCARB registers - User coherence operations

User coherence operations are broken into two types, block-oriented coherence and global coherence operations. The priority of these requests relative to other requests in the system varies as follows:

- Global user coherence: Always highest priority
- Block-oriented coherence: Always lowest priority

Because user coherence priority is fixed, the UCARB registers do not include a priority field. And because global user coherence operations are inherently highest priority, the MAXWAIT field programming applies only to block-oriented user coherence operations, not to global cache operations.

The UCARB[5:0] MAXWAIT field affects only the UMC (IVA\_UMC.UCARBU register) and the DMC (IVA\_DMC.UCARBD register). The priority values (being fixed) are assumed to be known at both the UMC and the DMC.

---

**Note:** The UCARB[5:0] MAXWAIT field (and the implied priorities) does not control the priority of coherence operations that result from DMA transactions or CPU transactions.

---

- IDMAARB registers - IDMA priority programming model

IDMA supports two active transfers at any time through IDMA channel 0 (used for memory to/from configuration bus transfers) and IDMA channel 1 (used for memory-to-memory transfers). The IDMAARB[5:0] MAXWAIT field is used to determine the maximum wait time for IDMA transactions. The priority level is not programmed through the IDMAARB register. Instead, the priority level is programmed directly through the IDMA control registers. In summary, IDMA transfer priority is:

- IDMA channel 0: Always highest priority
- IDMA channel 1: Programmable priority: the IVA\_IDMA.IDMA1\_COUNT[31:29] PRI field

For this reason, the IDMAARB registers do not include a priority field. The IDMAARB[5:0] MAXWAIT field affects not only the EMC (IVA\_IDMA.IDMAARBE register) but also the UMC (IVA\_UMC.IDMAARBU register) and the DMC (IVA\_DMC.IDMAARBD register).

---

**Note:** IDMA channel 0 has no need for priority inheritance, because it is always the highest priority transfer in the system.

However, if an IDMA channel 1 transfer and an IDMA channel 0 transfer are pending at the same instant, but the IDMA channel 1 queue is blocked because of contention with another requestor, the IDMA channel 1 transfer should briefly inherit the priority of the IDMA channel 0 transfer (which is always 0x0) so that the pending datapath on IDMA channel 1 can complete and the normal priority mechanism can take control.

---

- SDMAARB registers - Slave DMA priority programming model

The C64x + Megamodule slave DMA (SDMA) interface can support multiple active transfers at a time. The SDMAARB[5:0] MAXWAIT field controls the maximum wait time for all slave DMA transactions. The priority level is not programmed by the SDMAARB register. Instead, the priority level is dictated by the priority fields of the IVA\_TPCC.QUEPRI register.

The SDMAARB[5:0] MAXWAIT field does not affect only the EMC (IVA\_IDMA.SDMAARBE register), but also the UMC (IVA\_UMC.SDMAARBU register) and the DMC (IVA\_DMC.SDMAARBD register).

---

**Note:** Because of the pipelined nature of the VBUS interface, the C64x + Megamodule module can have multiple DMA transfers in flight at a time. To avoid priority inversion, the C64x + Megamodule must not only evaluate the priority of the transfer at the head of the EMC queue(s), but the priority of all transfers that have been accepted/queued on the VBUS interface(s), and of higher priority transfers that are queued in the device-level DMA infrastructure.

---

- MDMAARBE register - Master DMA priority programming model

The IVA\_IDMA.MDMAARBE[18:16] PRI field controls the submission priority for master DMA transactions (which are a result of cache misses or long-distance accesses to nonconfiguration space) and configuration bus transactions (long-distance accesses to configuration space or IDMA transfers to configuration space).

The IVA\_IDMA.MDMAARBE priority is different from other programmable priorities in the system, in that the priority value does not affect internal arbitration for resources. This PRI[3:0] value is simply used as the VBUS priority value for all transactions initiated by the DMA master interface or memory-mapped register configuration interface.

Arbitration for the internal half of the transfer depends on the initiator (which could be DSP CPU, PMC, or DMC) or user coherence (UMC), or IDMA, etc. Arbitration for the external half of the transfer is DMA-dependent, and should rely on the Vbus priority, which is copied from the IVA\_IDMA.MDMAARBE[18:16] PRI field.

---

**Note:** Because no internal arbitration results from the IVA\_IDMA.MDMAARBE register, there is no need for the MAXWAIT field in this register.

---

## 1.4.7 IWA2.2 Power Management

### 1.4.7.1 Clock Management

#### 1.4.7.1.1 Clock Configuration

The IWA2.2 subsystem receives one single-clock signal from the PRCM, the DPLL2\_ALWON.FCLK.

From the DPLL2\_ALWON.FCLK functional clock provided by the PRCM, three internal clocks (CD0\_CLK, CD1\_CLK, and CD2\_CLK) are generated by the IWA2.2 DPLL and SYSC modules:

- The frequency of the CD0\_CLK clock can be software-tuned with a PRCM register by setting the PRCM.CM\_CLKSEL1\_PLL\_IWA2 and PRCM.CM\_CLKSEL2\_PLL\_IWA2 registers.
- The CD1\_CLK clock is always a divide-by-two of the CD0\_CLK clock and its frequency cannot be changed by software.
- The CD2\_CLK clock is always a divide-by-two of the CD0\_CLK clock and its frequency cannot be changed by software.

For a complete description of the PRCM registers discussed in this section, see the *Power, Reset, and Clock Management* chapter.

#### 1.4.7.1.2 Clock Gating

- IWA2.2 subsystem

The IWA2.2 internal clocks can be hardware-disabled by the PRCM when the MSTANDBY/WAIT handshake protocol occurs. To configure the PRCM so that IWA2.2 internal clocks are hardware-supervised, set the PRCM.CM\_AUTOIDLE\_PLL\_IWA2[2:0] AUTO\_IWA2\_DPLL field to 0x1. When the IWA2.2 subsystem does not require its internal clocks, they can be disabled at the PRCM level by setting the PRCM.CM\_FCLKEN\_IWA2[0] EN\_IWA2 bit to 0.

For a complete description of these PRCM registers, see the *Power, Reset, and Clock Management* chapter.

- SYSC module

The IWA2.2 SYSC module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state is operated with no cycle latency penalty.

The automatic clock-gating feature is enabled by setting the IVA\_SYSC.SYSC\_SYSCONFIG[0] AUTOIDLE bit to 1 (default value). This feature can be disabled by setting the IVA\_SYSC.SYSC\_SYSCONFIG[0] AUTOIDLE bit to 0 and making the clock free-running.

- WUGEN module

The IWA2.2 WUGEN module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state operates with no cycle latency penalty.

Automatic clock gating is enabled by setting the IVA\_WUGEN.WUGEN\_SYSCONFIG[0] AUTOIDLE bit to 1 (default mode). The clock can be made free-running by setting the IVA\_WUGEN.WUGEN\_SYSCONFIG[0] AUTOIDLE bit to 0.

- TPCC from EDMA module

The EDMA (or TPCC) module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-nongated to clock-gated state operates with no cycle latency penalty.

Automatic clock gating is enabled by default. The software user can disable auto-clock gating by setting the TPCC\_CLKGDIS[0] CLKGDIS bit to 1. In this case, all TPCC internal clocks are free-running.

---

**Note:** To save power, it is recommended to not disable TPCC clock gating and to leave the TPCC\_CLKGDIS register at its reset value.

---

### 1.4.7.2 Reset Management

In addition to hardware reset signals generated by the PRCM, the IVA2.2 subsystem can be reset by software control.

The three DSP power domain software resets (DSP\_RST1, DSP\_RST2, and DSP\_RST3) are partial warm-reset sources. These software resets map to the PRCM.RM\_RSTCTL\_IVA2[0] RST1\_IVA2 bit, the RM\_RSTCTL\_IVA2[1] RST2\_IVA2 bit, and the PRCM.RM\_RSTCTL\_IVA2[2] RST3\_IVA2 bit, respectively, in the PRCM register RM\_RSTCTL\_IVA2.

Setting these 3 bits to 1 performs a software reset to the IVA2.2 subsystem.

The reset status is logged in the PRCM.RM\_RSTST\_IVA2[8] IVA2\_SW\_RST1 read-only bit for IVA2\_RST1 software reset, the PRCM.RM\_RSTST\_IVA2[9] IVA2\_SW\_RST2 read-only bit for IVA2\_RST2 software reset, and the PRCM.RM\_RSTST\_IVA2[10] IVA2\_SW\_RST3 read-only bit for IVA2\_RST3 software reset.

For a complete description of these PRCM registers, see the *Power, Reset, and Clock Management* chapter.

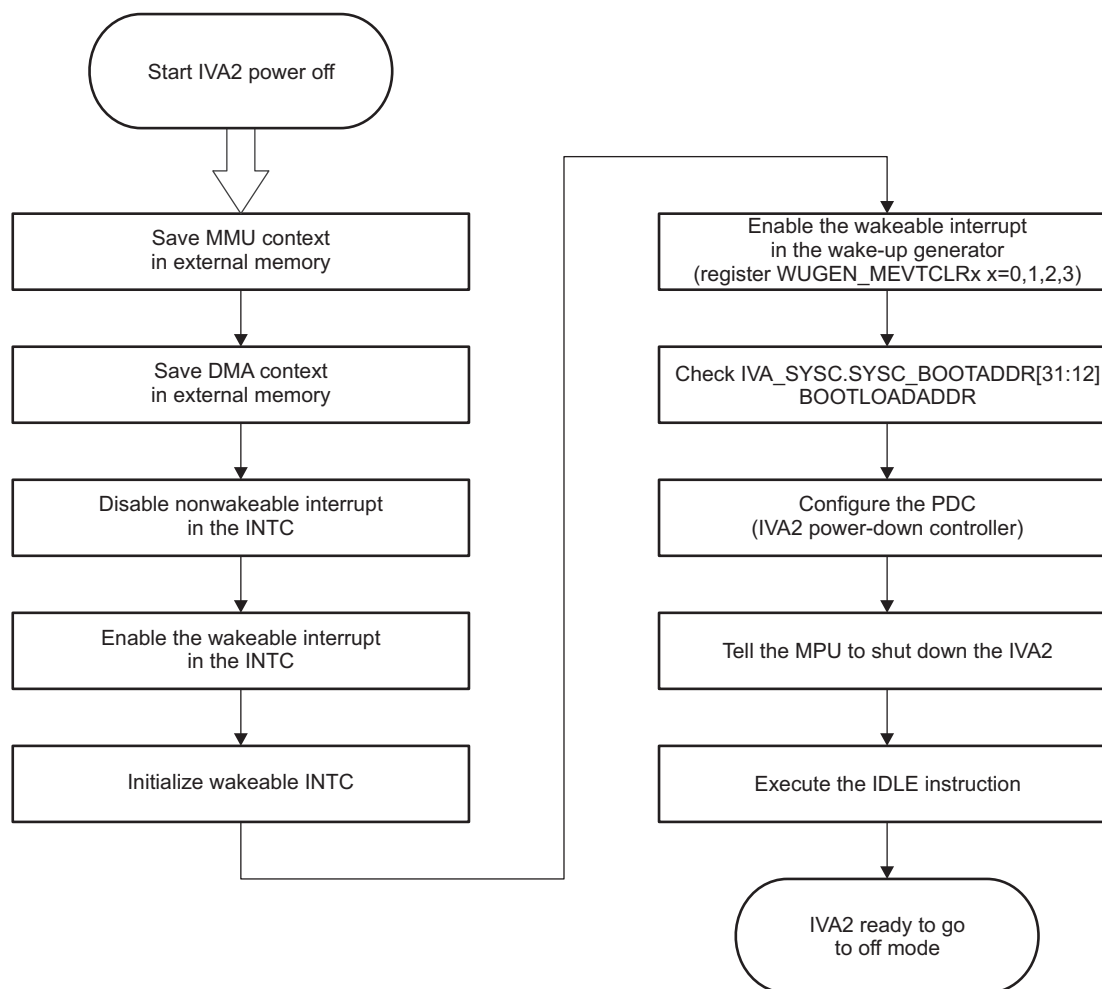

---

**Note:** Software reset can be applied only while the IVA2.2 subsystem is in clock-off mode.

---

### 1.4.7.3 Power-Down and Wake-Up Management

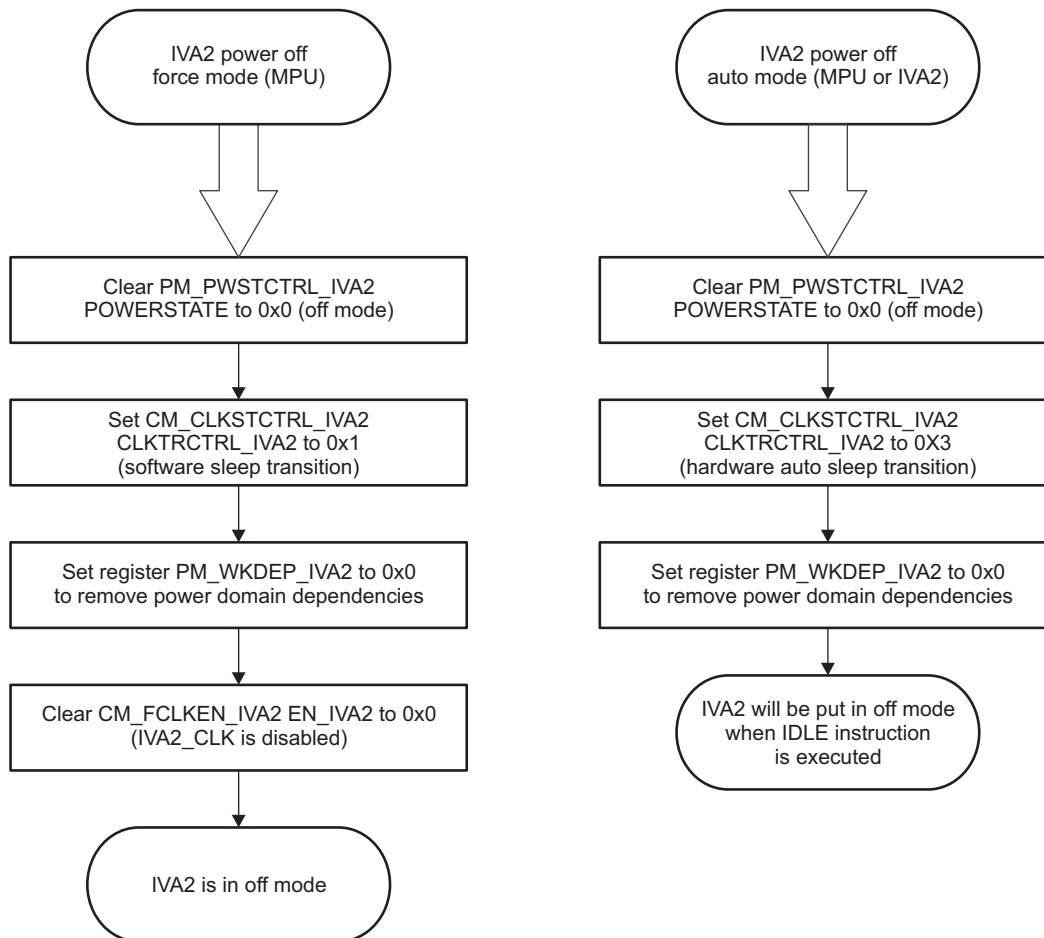

- C64x + Megamodule power-down controller (PDC)  
The C64x + Megamodule embeds a PDC block that allows power-down management by software. Individual C64x + Megamodule blocks such as C64x + Megamodule CPU, PMC, DMC, EMC, and UMC can be powered off by the PDC.
- This software control is ensured by the IVA\_SYS.PDCCMD register:
  - By setting the IVA\_SYS.PDCCMD[16] GEMPD bit to 1, the user enables power-down management during idle mode.
  - By setting the IVA\_SYS.PDCCMD xMCLOG[1:0] and IVA\_SYS.PDCCMD xMCMEM[1:0] fields (x = {P, D, U}), the user controls the XMC clock-gating and standby memory modes. For example, DMC is controlled with the IVA\_SYS.PDCCMD[5:4] DMCLOG and IVA\_SYS.PDCCMD[7:6] xMCMEM fields.
  - The programming sequence for transition to clock-off state is as follows:  
Before executing the IDLE instruction, the user must perform the following sequence:
    1. Write 1 to the IVA\_SYS.PDCCMD[16] GEMPD bit (standby state); by default, the IVA\_SYS.PDCCMD xMCLOG[1:0] and IVA\_SYS.PDCCMD xMCMEM[1:0] (x = {P, D, U}) field values are all 0x1, so that module clock gating is enabled and standby mode of memories is statically activated after the IDLE instruction executes.
    2. Mask all interrupts not intended to wake up the IVA2.2 subsystem.
    3. Program the PRCM so that IVA2.2 clocks are cut on IVA2.2 standby. For more information, see the *Power, Reset, and Clock Management* chapter.
    4. Read back all the written registers to ensure write completion.
 The user must also ensure that no other instruction is executed parallel to the IDLE instruction. When a clock stop request is asserted, the PDC\_INT event (EVT118, see [Table 1-3](#)) is generated to the C64x + Megamodule IC module to inform the DSP CPU to initiate a power-down sequence. For more information about interrupt management, see [Section 1.4.5, Interrupt Management](#).
- Programming sequence for transition to power-off state:  
Before executing the IDLE instruction, the user must perform the sequence shown in [Figure 1-30](#).

**Figure 1-30. IVA2 Power Off**

iva22-045

The user must also ensure that no other instruction is executed parallel to the IDLE instruction. When IVA2 is ready to go to off mode, there are two ways to completely shut down IVA2 subsystem (see [Figure 1-31](#)):

Figure 1-31. IVA2 Power Down

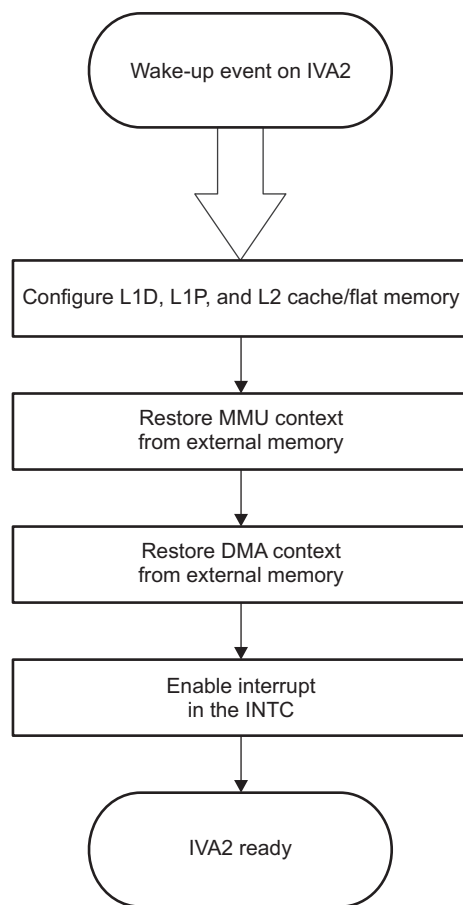

iva22-046

#### CAUTION

The IVA2 clock must not be stopped manually; otherwise, the WUGEN module inside the IVA2 has no functional clock and cannot wake up the IVA subsystem.

When the IVA2 is shut down, it can be waked up by an external event. The boot code executed after wakeup must include at least the following steps (see [Figure 1-32](#)):

**Figure 1-32. IVA2 Wake Up**

iva22-047

#### 1.4.7.4 Powering Down L2\$ Memory While IVA2 is Active

If the L2\$ is unused while the DSP is active, the IVA2.2 can completely switch off the 96-KB SRAM attached to the L2\$ controller. This typically happens when the DSP is running at a low frequency (for instance, at the same frequency as the SDRAM) where L2\$ is not justified. The alternative is to switch off L2\$ SRAM completely, losing all L2-cache content and memory-mapped SRAM (from 0x10800000 to 0x1080FFFF). It is impossible to put the SRAM in low-leakage mode and retain data/program while the DSP is active. Also, L2 cache SRAM is the only memory/cache that supports this off mode while DSP is active. L1D and L1P cache SRAM off modes are not supported while DSP is active.

The sequence to enter L2\$ off mode while DSP is active follows:

1. Save L2CFG and disable the L2\$ by converting L2-cache SRAM to memory-mapped SRAM only (96KB): L2CFG.L2MODE = 0x0.
2. Read back L2CFG to ensure that Step 1 is complete.
3. Save L2MPPAj (i = 0 to 31) and write 0x0 to the L2MPPAj (i = 0 to 31) registers to report access to L2 memory (for debug) and enable associated permission check interrupt and/or exception.
4. Configure the PRCM to switch off L2:  
PRCM.PM\_PWSTCTRL\_IVA2.SHAREDL2CACHEFLATONSTATE = 0x0.
5. Read back PRCM.PM\_PWSTCTRL\_IVA2 to ensure that Step 4 is complete.

After this sequence, the user must not access the L2 memory. If this happens (typically in code under debug), a memory-protection interrupt and/or exception is taken.

The sequence to exit L2\$ off mode (while DSP is active) follows:

1. Configure the PRCM to switch on L2:  
PRCM.PM\_PWSTCTRL\_IVA2.SHARED\_L2CACHEFLATONSTATE = 0x3.
2. Read back PRCM.PM\_PWSTCTRL\_IVA2 to ensure that Step 1 is complete.
3. Restore L2MPPAj (i = 0 to 31).
4. Restore L2CFG.
5. Read back PRCM.PM\_PWSTCTRL\_IVA2 to ensure that Step 4 is complete.

---

**Note:** After this sequence, L2\$ is empty and content in L2\$-SRAM configured as memory-mapped is lost.

---

---

**Note:** This mode does not provide large power savings, but is provided in IVA2.2 as an enabler for power-management software development, anticipating that leakage is a major contributor to power consumption, even in active mode.

---

### 1.4.8 Error Identification Process

Several mechanisms are available in the IVA2.2 subsystem to report errors at different levels.

#### 1.4.8.1 Error Reporting for IDMA Module

The IDMA has its own error-reporting mechanism. The C64x + Megamodule implements an error register in EMC (IVA\_IDMA.IBUSERR) that latches errors for external invalid transactions on either the DMA (MDMA) bus or the configuration (CFG) bus. Errors are detected on the CFG and MDMA write status or read status interfaces. If an error is received and the corresponding command is an invalid transaction, the IVA\_IDMA.IBUSERR[31:29] ERR, IVA\_IDMA.IBUSERR[10:8] XID, and IVA\_IDMA.IBUSERR[2:0] STAT fields are updated accordingly. An error signaled through a non-0 read status is detected on the read data/status interface or a non-0 write status on the write status interface. Alternately, the EMC records an error if a read or write status response is detected for an unrecognized write ID.

---

**Note:** The user must ensure that the EMC detects/stores error information only for the first detected error on either the MDMA or CFG bus, regardless of whether it is a read or write status. In other words, a single error register (IVA\_IDMA.IBUSERR) is shared by read and write errors and by the MDMA bus and the CFG bus, and only the first error is stored. If a read error and a write error are detected at the same time, the write status error is given higher priority and is latched into the IVA\_IDMA.IBUSERR register.

---

When an error is detected and stored in the IVA\_IDMA.IBUSERR register, the EMC\_BUSERR event (EVT127, see [Table 1-3](#)) is available as a system event that can be selected as either a DSP CPU interrupt or an exception event.

The user can clear latched errors by writing 1 to the IVA\_IDMA.IBUSERRCLR[0] CLR bit.

#### 1.4.8.2 Error Reporting for EDMA Module

The TPTC and TPCC blocks of the EDMA module also contain registers to inform the user of a problem during IVA2.2 external DMA communication.

##### TPCC Block

The TPCC provides a single error interrupt output CCERRINT (EVT38, see [Table 1-3](#)) that consolidates the error conditions:

- QDMA missed events (stored in the TPCC\_QEMR register)
- DMA missed events (stored in the TPCC\_EMER register)
- Transfer completion code error (stored in the TPCC\_CCERR[16] TCCERR bit)
- Queue threshold error events (stored in the TPCC\_CCERR[n] QTHRXCDn bit, n = {0,1})

When an error is detected, the CCERRINT event is asserted, because error events do not have enables.

---

**Note:** The CCERRINT event follows the same conventions as other TPCC interrupt outputs. When the error interrupt condition transitions from a no-errors-are-set state to at least one error set, the error output (CCERRINT) pulses high for one TPCC clock cycle. If additional errors are latched before the original error is cleared by the user, the TPCC does not generate additional interrupt pulses. The software must poll all bits during execution of the ISR, and clear all error conditions, so that subsequent error pulses can be generated by the TPCC block.

---

Error interrupts can be set and/or reevaluated by writes to the TPCC\_EEVAL register.

### TPTC Block

The TPTC can also detect several error conditions:

- Read status or write status errors in the TPTCj\_ERRSTAT[0] BUSERR status bit
- TR error in the TPTCj\_ERRSTAT[2] TRERR status bit
- MMR address error in the TPTCj\_ERRSTAT[3] MMRAERR status bit

Errors are recorded in the TPTCj\_ERRSTAT register, regardless of whether they are enabled. They can be cleared from the TPTCj\_ERRSTAT register only by writing 1 to the corresponding bit of the IVA\_TPTCj\_ERRCLR register.

The error details register (IVA\_TPTCj\_ERRDET) contains additional information about the first read status error or write status error detected. Future errors are bit-recorded until the TPTCj\_ERRDET register is cleared.

If read status and write status are returned to the TPTC in the same cycle, the read or write status value that has an error (nonzero) is latched in the TPTCj\_ERRDET register and the TPTCj\_ERRSTAT[0] BUSERR bit is set. If both read and write status are nonzero, the write status is given priority for setting the TPTCj\_ERRDET register. The TPTCj\_ERRDET register is cleared by writing 1 to the TPTCj\_ERRCLR[0] BUSERR bit.

If an error is enabled (by the TPTCj\_ERREN register bits), the first occurrence of an enabled error generates a pulsed interrupt to the CPU by the TCERRINT event output (TCERRINT0 with EVT39 for TPTG0 and TCERRINT1 with EVT40 for TPTG1, respectively; see [Table 1-3](#)). Subsequent errors do not generate a new pulse until all accumulated errors are cleared by the CPU. The CPU clears bits in the TPTCj\_INTSTAT register by writing 1 to the corresponding bit(s) of the TPTCj\_NTCLR register.

#### 1.4.8.3 Error Reporting for the L3 Interconnect

L3 interconnect out-of-band errors are also reported by the external L3 interrupt signal (I3\_ia\_iva2\_initSErr\_o). This signal corresponds to the EVT84 event and is directly connected to the IVA2.2\_nIRQ[39] DSP CPU interrupt line. For more information about L3 interconnect error reporting, see the *Interconnect* chapter.

#### 1.4.9 Recommendations for Static Settings

The following static settings are recommended:

- SYSC.SYSC\_LICFG0.DMATRUECOMPEN = 1; // DMA last write is nonposted.
- SYSC.SYSC\_LICFG0.GEMTRUECOMPEN = 1; // C64x + Megamodule last write is nonposted.
- SYSC.SYSC\_LICFG0.GEMBURSTOPTEN = 1; // C64x + Megamodule burst optimization

Ensure that the following setting is carefully set:

- All 2D DMA transfers source and/or destination are to a VRFB view (tiling structure):
  - // DMA 2D burst optimization
  - SYSC.SYSC\_LICFG0.DMA2DOPTEN = 1

**Note:** If the preceding condition is not set accurately, setting the DMA2DOPTEN optimization can degrade performance.

---

**Notes:**

1. A super-section type MMU page (16MB) must be defined for that VRFB view.
2. When the SYSC.SYSC\_LICFG0.PAGEXINGEN is set to 1, a 2D DMA should not cross a MMU page boundary. When this bit is set, it disables the hardware check mechanism for better performance (but the user should ensure that 2D DMA does not cross MMU pages).

Therefore, ensure that the following setting is carefully set:  
SYSC.SYSC\_LICFG0.PAGEXINGEN = 1.

---

**Note:** If the preceding condition is not set accurately, setting the PAGEXINGEN optimization can cause undefined results, including deadlock situations.

---

## 1.5 IVA2.2 Subsystem Registers

IVA hardware accelerators are not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this feature.

Table 1-16 lists the IVA2.2 memory space mapping as seen by the IVA2.2 C64x + Megamodule.

**Table 1-16. Instance Summary**

Module Name	Base Address	Size
IC	0x0180 0000	64K bytes
SYS	0x0181 0000	64K bytes
IDMA	0x0182 0000	64K bytes
XMC	0x0184 0000	64K bytes
TPCC	0x01C0 0000	64K bytes
TPTC0	0x01C1 0000	1K byte
TPTC1	0x01C1 0400	1K byte
SYSC	0x01C2 0000	4K bytes
WUGEN	0x01C2 1000	4K bytes
Video Hardware Accelerator	0x0008 0000	22K bytes
IA_GEM	0x000F 8800	1K bytes
IA_EDMA	0x000F 8C00	1K bytes

For more information on the IVA2.2 memory mapping, see the *Memory Mapping* chapter.

**Note:** The MMU2 (IVA2.2 MMU) registers are described in Chapter 8, *Memory Management Units*. (The MMU base address is 0x5D00 0000 on the L3 interconnect).

### CAUTION

The IVA2.2 registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

### 1.5.1 Register Mapping Summary

**Table 1-17. IC Register Mapping Summary**

Bits	Field Name	Description	Type	Reset
31:16	Reserved	write 0 for future compatibility Read returns 0	RW	0
15	IDM15	Dropped event mask for CPU interrupt #15	RW	0
14	IDM14	Dropped event mask for CPU interrupt #14	RW	0
13	IDM13	Dropped event mask for CPU interrupt #13	RW	0
12	IDM12	Dropped event mask for CPU interrupt #12	RW	0
11	IDM11	Dropped event mask for CPU interrupt #11	RW	0
10	IDM10	Dropped event mask for CPU interrupt #10	RW	0
9	IDM9	Dropped event mask for CPU interrupt #9	RW	0
8	IDM8	Dropped event mask for CPU interrupt #8	RW	0
7	IDM7	Dropped event mask for CPU interrupt #7	RW	0
6	IDM6	Dropped event mask for CPU interrupt #6	RW	0
5	IDM5	Dropped event mask for CPU interrupt #5	RW	0
4	IDM4	Dropped event mask for CPU interrupt #4	RW	0
3:0	Reserved	write 0 for future compatibility Read returns 0	RW	0

### 1.5.2.12 EVTASRT

**Table 1-38. EVTASRT**

<b>Address Offset</b>	0x0000 01C0																														
<b>Physical address</b>	0x0180 01C0															<b>Instance</b>	IVA2.2 GEMIC														
<b>Description</b>	Event Assert Register																														
<b>Type</b>	W																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																							MXF7	MXF6	MXF5	MXF4	MXF3	MXF2	MXF1	MXF0	
<b>Bits</b>	<b>Field Name</b>		<b>Description</b>																			<b>Type</b>				<b>Reset</b>					
31:8	Reserved		write 0 for future compatibility																			W				0					
7	MXF7		Event Assert output #7 EA7 = 0: No effect EA7 = 1: EVTOUT7 pulsed high for 4 clk1 cycles, then low.																			W				0					
6	MXF6		Event Assert output #6 EA6 = 0: No effect EA6 = 1: EVTOUT6 pulsed high for 4 clk1 cycles, then low.																			W				0					
5	MXF5		Event Assert output #5 EA5 = 0: No effect EA5 = 1: EVTOUT5 pulsed high for 4 clk1 cycles, then low.																			W				0					
4	MXF4		Event Assert output #4 EA4 = 0: No effect EA4 = 1: EVTOUT4 pulsed high for 4 clk1 cycles, then low.																			W				0					
3	MXF3		Event Assert output #3 EA3 = 0: No effect EA3 = 1: EVTOUT3 pulsed high for 4 clk1 cycles, then low.																			W				0					
2	MXF2		Event Assert output #2 EA2 = 0: No effect EA2 = 1: EVTOUT2 pulsed high for 4 clk1 cycles, then low.																			W				0					
1	MXF1		Event Assert output #1 EA1 = 0: No effect EA1 = 1: EVTOUT1 pulsed high for 4 clk1 cycles, then low.																			W				0					
0	MXF0		Event Assert output #0 EA0 = 0: No effect EA0 = 1: EVTOUT0 pulsed high for 4 clk1 cycles, then low.																			W				0					

### 1.5.3 SYS Register Descriptions

This section provides information about the SYS Module. Each register in the module is described separately below.

#### 1.5.3.1 PDCCMD

**Table 1-39. PDCCMD**

Address Offset	0x0000 0000																															
Physical address	0x0181 0000															Instance	IVA2.2 GEMSYS															
Description	Power-Down Command Register																															
Type	RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																GEMPD	EMCMEM	EMCLOG	UMCMEM	UMCLOG	DMCMEM	DMCLOG	PMCMEM	PMCLOG								
Bits	Field Name		Description																				Type		Reset							
31:17	Reserved		Write 0s for future compatibility. Read returns 0.																				RW		0x0000							
16	GEMPD		Power-down during IDLE: GEMPD = 0: Normal operation. Do not power-down CPU or C64x + Megamodule when CPU is IDLE. GEMPD = 1: Sleep mode. Power-down CPU and C64x + Megamodule when CPU enters IDLE state																				RW		0							
15:14	EMCMEM		SRAM Sleep Modes Determines the RAM sleep modes used by the EMC for powering-down internal memories.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1																				RW		0x1							
13:12	EMCLOG		Logic Clock Gating Modes. Determines to what degree the EMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules regions when C64x + Megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when C64x + Megamodule is in standby (pmc_pd_pdstat[1:0] = 11)																				RW		0x1							
11:10	UMCMEM		SRAM Sleep Modes Determines the RAM sleep modes used by the UMC for powering-down L2 pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1																				RW		0x1							
9:8	UMCLOG		Logic Clock Gating Modes. Determines to what degree the UMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules regions when C64x + Megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when C64x + Megamodule is in standby (pmc_pd_pdstat[1:0] = 11)																				RW		0x1							

Bits	Field Name	Description	Type	Reset
7:6	DMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the DMC for powering-down L1D pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
5:4	DMCLOG	Logic Clock Gating Modes. Determines to what degree the DMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules regions when C64x + Megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when C64x + Megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
3:2	PMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the PMC for powering-down L1P pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
1:0	PMCLOG	Logic Clock Gating Modes. Determines to what degree the PMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules regions when C64x + Megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when C64x + Megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1

### 1.5.3.2 REVID

**Table 1-40. REVID**

<b>Address Offset</b>	0x0000 2000																																
<b>Physical address</b>	0x0181 2000																<b>Instance</b>	IVA2.2 GEMSYS															
<b>Description</b>	C64x + Megamodule Revision ID Register																																
<b>Type</b>	R																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
VERSION																REVISION																	
<b>Bits</b>		<b>Field Name</b>						<b>Description</b>														<b>Type</b>				<b>Reset</b>							
31:16		VERSION						Functional implementation of C64x + Megamodule 0x0002 : MidGEM														R				0x0002							
15:0		REVISION						Physical implementation of C64x + Megamodule version														R				0x0000							

## 1.5.4 IDMA Register Descriptions

This section provides information about the IDMA Module. Each register in the module is described separately below.

### 1.5.4.1 IDMA0\_STAT

**Table 1-41. IDMA0\_STAT**

<b>Address Offset</b>	0x0000 0000																																																																																														
<b>Physical address</b>	0x0182 0000								<b>Instance</b>	IVA2.2 GEMIDMA																																																																																					
<b>Description</b>	IDMA Channel 0 Status Register																																																																																														
<b>Type</b>	R																																																																																														
<table><tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr><tr><td colspan="28">Reserved</td><td>PEND</td><td>ACTV</td></tr></table>																																		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Reserved																												PEND	ACTV
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																																																																
Reserved																												PEND	ACTV																																																																		
<b>Bits</b>	<b>Field Name</b>		<b>Description</b>																								<b>Type</b>		<b>Reset</b>																																																																		
31:2	Reserved		Reads return 0s																								R		0																																																																		
1	PEND		Pending transfer: Set when control registers are written to by the CPU and there is already an active transfer in progress (ACTV = 1) and cleared when the transfer becomes active. PEND = 1: Transfer is pending PEND = 0: No pending transfer																								R		0																																																																		
0	ACTV		Active transfer: Set when channel 0 begins reading data from the source address and cleared following the last write to the destination address. ACTV = 1: Active transfer ACTV = 0: No active transfer																								R		0																																																																		

### 1.5.4.2 IDMA0\_MASK

**Table 1-42. IDMA0\_MASK**

31:5		DESTADDR		Destination Address: Must point to a 32-byte-aligned (e.g. window aligned) memory location local to C64x + Megamodule or to a valid configuration register space.																																												RW		0x0000000													
4:0		Reserved		Write 0s for future compatibility. Read returns 0.																																												RW		0x00													

### 1.5.4.5 IDMA0\_COUNT

**Table 1-45. IDMA0\_COUNT**

<b>Address Offset</b>	0x0000 0010																																
<b>Physical address</b>	0x0182 0010								<b>Instance</b>	IVA2.2 GEMIDMA																							
<b>Description</b>	IDMA Channel 0 Count Register																																
<b>Type</b>	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			INT	Reserved																								COUNT			

Bits	Field Name	Description	Type	Reset
31:29	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0
28	INT	CPU interrupt enable INT = 1: Interrupt CPU (IDMA_INT0) on completion INT = 0: Do not interrupt CPU on completion	RW	0
27:4	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x000000
3:0	COUNT	Window COUNT = 0000: Transfer to/from one 32-word window COUNT = n: Transfer to/from n+1 32-word windows	RW	0x0

### 1.5.4.6 IDMA1\_STAT

**Table 1-46. IDMA1\_STAT**

<b>Address Offset</b>	0x0000 0100																																
<b>Physical address</b>	0x0182 0100																<b>Instance</b>	IVA2.2 GEMIDMA															
<b>Description</b>	IDMA Channel 1 Status Register																																
<b>Type</b>	R																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reserved																																PEND	ACTV

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x00000000
1	PEND	Pending transfer: Set when control registers are written to by the CPU and there is already an active transfer in progress (ACTV = 1) and cleared when the transfer becomes active. PEND = 1: Transfer is pending PEND = 0: No pending transfer	R	0
0	ACTV	Active transfer: Set when channel 1 begins reading data from the source address and cleared following the last write to the destination address. ACTV = 1: Active transfer ACTV = 0: No active transfer	R	0

### 1.5.4.7 IDMA1\_SOURCE

**Table 1-47. IDMA1\_SOURCE**

<b>Address Offset</b>	0x0000 0108																																
<b>Physical address</b>	0x0182 0108																<b>Instance</b>	IVA2.2 GEMIDMA															
<b>Description</b>	IDMA Channel 1 Source Address Register																																
<b>Type</b>	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SOURCEADDR																															

Bits	Field Name	Description	Type	Reset
31:0	SOURCEADDR	Source Address: Must point to a word-aligned memory location local to C64x + Megamodule. When performing a block fill (IDMA1_COUNT.FILL = 1) the source address is the fill value. Note that when performing a Fill Mode transfer all 32-bits of the SOURCEADDR are writeable and when performing a linear transfer the two LSBs are implemented as 00b.	RW	0x00000000

### 1.5.4.8 IDMA1\_DEST

**Table 1-48. IDMA1\_DEST**

<b>Address Offset</b>	0x0000 010C																															
<b>Physical address</b>	0x0182 010C								<b>Instance</b> IVA2.2 GEMIDMA																							
<b>Description</b>	IDMA Channel 1 Destination Address Register																															
<b>Type</b>	RW																															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
DESTADDR																																Reserved

Bits	Field Name	Description	Type	Reset
31:2	DESTADDR	Destination Address: Must point to a word-aligned memory location local to C64x + Megamodule.	RW	0x00000000
1:0	Reserved	Reads return 0s Write 0 for further compatibility	R	0x00

### 1.5.4.9 IDMA1\_COUNT

**Table 1-49. IDMA1\_COUNT**

<b>Address Offset</b>	0x0000 0110																																
<b>Physical address</b>	0x0182 0110								<b>Instance</b>	IVA2.2 GEMIDMA																							
<b>Description</b>	IDMA Channel 0 Count Register																																
<b>Type</b>	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRI			INT	Reserved											FILL	COUNT											Reserved				

Bits	Field Name	Description	Type	Reset
31:29	PRI	Transfer priority. Used for arbitration between CPU and DMA accesses when there are conflicts. PRI = 111b: Low priority PRI = 000b: High priority	RW	0x0
28	INT	CPU interrupt enable INT = 1: Interrupt CPU (IDMA_INT1) on completion INT = 0: Do not interrupt CPU on completion	RW	0
27:17	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x000
16	FILL	Block fill: FILL = 1: Perform a block fill using the Source address field as the fill value to the memory buffer pointed to by the Destination address field. FILL = 0: Block transfer from the source address to the destination address.	RW	0
15:2	COUNT	16-bit byte count. Must be a multiple of 4 bytes. A transfer count of zero will not transfer any data, but will generate an interrupt if requested in the INT field.	RW	0x0000
1:0	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0

### 1.5.4.10 CPUARBE

**Table 1-50. CPUARBE**

Address Offset	0x0000 0200																														
Physical address	0x0182 0200								Instance								IVA2.2 GEMIDMA														
Description	CPU Arbitration Control																														
Type	RW																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													PRI			Reserved										MAXWAIT					
Bits	Field Name							Description															Type				Reset				
31:19	Reserved							Write 0s for future compatibility. Read returns 0.															RW				0x000				
18:16	PRI							Priority															RW				0x1				
								0x0: Highest priority																							
								0x1: 2nd highest priority																							
								0x2: 3rd highest priority

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x0000
15:8	FLTID	Faulted ID: VBUS PrivID of faulting requestor. This field is valid only if LE is zero.	R	0x00
7	SECE	0: No nonsecure request to a secure page has been made 1: nonsecure request to a secure page has been made	R	0
6	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x0
5:0	ATYP	Access type	R	0x00

### 1.5.4.16 ICFGMPFCR

**Table 1-56. ICFGMPFCR**

<b>Address Offset</b>	0x0000 0308	<b>Instance</b>	IVA2.2 GEMIDMA
<b>Physical address</b>	0x0182 0308		
<b>Description</b>	ICFG Memory Protection Fault Command Register		
<b>Type</b>	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																															MPFCLR

Bits	Field Name	Description	Type	Reset
31:1	Reserved	Write 0s for future compatibility. Read returns 0.	W	
0	MPFCLR	Write 0: No effect Write 1: Clear fault logged information	W	0

### 1.5.4.17 IBUSERR

**Table 1-57. IBUSERR**

Address Offset		0x0000 0400	
Physical address	0x0182 0400	Instance	IVA2.2 GEMIDMA
Description	Bus Access Error Register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ERR				Reserved												XID				Reserved				STAT							

Bits	Field Name	Description	Type	Reset
31:29	ERR	Error detected 0x0: No error 0x1: MDMA Read Status Error detected 0x2: MDMA Write Status Error detected 0x3: CFG Read Status Error detected 0x4: CFG Write Status Error detected	R	0x00000
28:11	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x00
10:8	XID	Transaction ID Stores the Transaction ID when an error is detected on the response. Value should match the command id for the access that resulted in an error.	R	0x0
7:3	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x00
2:0	STAT	Transaction Status Stores the non-zero status/error code that was detected on the response to an access 0x0: Success (should not cause error to be latched), or unrecognized RID/WID (should cause error to be latched) 0x1: Addressing error 0x2: Privilege error 0x3: Timeout error 0x4: Data error 0x7: Exclusive-operation failure	R	0x0

### 1.5.4.18 IBUSERRCLR

**Table 1-58. IBUSERRCLR**

<b>Address Offset</b>	0x0000 0404																<b>Instance</b>	IVA2.2 GEMIDMA															
<b>Physical address</b>	0x0182 0404																																
<b>Description</b>	Bus Access Error Clear																																
<b>Type</b>	W																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																															CLR

Bits	Field Name	Description	Type	Reset
31:1	Reserved	Write 0s for future compatibility. Read returns 0.	W	0x00000000
0	CLR	Clear Error CLR = 0: Writes of 0 have no effect. CLR = 1: Write of 1 clears all bits in the IBUSERR register. Once an error is detected, the MDMA Error register must be cleared before additional errors can be detected/stored.	W	0

## 1.5.5 XMC Register Descriptions

This section provides information about the XMC module, which contains the registers related to the three memory controllers of MidGEM: UMC, PMC, and DMC. Each register in the module is described separately below.

### 1.5.5.1 L2CFG

**Table 1-59. L2CFG**

Address Offset		0x0000 0000																Instance		IVA2.2 GEMXMC															
Physical address		0x0184 0000																																	
Description		L2 cache configuration register																																	
Type		RW																																	
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
Reserved				NUM_MM				Reserved				MMID				Reserved				NOINIT	IP	ID	Reserved			L2CC		L2MODE							
Bits	Field Name			Description																Type			Reset												
31:28	Reserved			Write 0s for future compatibility. Read returns 0.																R			0x0												
27:24	NUM_MM			Number of megamodules -1 (always 0 for IVA2)																R			0x0												
23:20	Reserved			Write 0s for future compatibility. Read returns 0.																R			0x0												
19:16	MMID			Megamodule ID (always 0x0 for IVA2)																R			0x0												
15:11	Reserved			Write 0s for future compatibility. Read returns 0.																W			0x00												
10	NOINIT			No init upon cache config: when written '1', cache config is restored without reinitializing cache context (tags, validity bits) (this is assumed here that the restored cache settings are the same as prior to the execution of the IDLE instruction) when written '0', cache context is reinitialized (cache content is indirectly lost) this bit is always read as 0																W			0												
9	IP			Global L1P invalidate (for backward compatibility, deprecated)																W			0												
8	ID			Global L1D invalidate (for backward compatibility, deprecated)																W			0												
7:5	Reserved			Write 0s for future compatibility. Read returns 0.																W			0x0												
4:3	L2CC			L2 cache control																RW			0x0												
				0x0: L2 cache operates normally																															
				0x1: L2 Cache is frozen																															
				0x2: L2 cache is bypassed																															
2:0	L2MODE			L2 Configuration Register																RW			0x0												
				0x0: 0KB of L2 Cache																															
				0x1: 32KB of L2 Cache																															
				0x2: 64KB of L2 Cache																															

### 1.5.5.2 L1PCFG

**Table 1-60. L1PCFG**

<b>Address Offset</b>	0x0000 0020	<b>Instance</b>	IVA2.2 GEMXMC
<b>Physical address</b>	0x0184 0020		
<b>Description</b>			
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																															L1PMODE

Bits	Field Name	Description	Type	Reset
31:3	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00000000
2:0	L1PMODE	L1P Configuration Register	RW	0x0
		0x0: 0KB of L1P Cache		
		0x1: 4KB of L1P Cache		
		0x2: 8KB of L1P Cache		
		0x3: 16KB of L1P Cache		
		0x4: Maximum cache (32KB of L1P Cache)		

### 1.5.5.3 L1PCC

**Table 1-61. L1PCC**

<b>Address Offset</b>	<b>0x0000 0024</b>																																
<b>Physical address</b>	0x0184 0024								<b>Instance</b>	IVA2.2 GEMXMC																							
<b>Description</b>	L1P Configuration Register																																
<b>Type</b>	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													POPER			Reserved													OPER		

Bits	Field Name	Description	Type	Reset
31:19	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x0000
18:16	POPER	Previous value of the OPER field	R	0x0
		Read 0x0: L1P cache operates normally		
		Read 0x1: L1P Cache is frozen		
15:3	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
2:0	OPER	DMC operation control	RW	0x0
		0x0: L1P cache operates normally		
		0x1: L1P Cache is frozen		

### 1.5.5.4 L1DCFG

**Table 1-62. L1DCFG**

<b>Address Offset</b>	0x0000 0040																															
<b>Physical address</b>	0x0184 0040																<b>Instance</b> IVA2.2 GEMXMC															
<b>Description</b>	L1D resets to Maximal cache mode using dmc_default_cachemode tie-off input.																															
<b>Type</b>	RW																															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																												L1DMODE			

Bits	Field Name	Description	Type	Reset
31:3	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00000000
2:0	L1DMODE	L1D Configuration Register	RW	0x0

## 1.5.6 TPCC Register Descriptions

This section provides information about the TPCC module. Each register in the module is described separately below.

### 1.5.6.1 TPCC\_PID

**Table 1-106. TPCC\_PID**

<b>Address Offset</b>	0x0000																																<b>Instance</b>																IVA2.2 TPCC															
<b>Physical address</b>	0x01C0 0000																																																															
<b>Description</b>	Peripheral ID Register																																																															
<b>Type</b>	R																																																															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SCHEME		Reserved		FUNC												RTL				MAJOR				CUSTOM		MINOR					

Bits	Field Name	Description	Type	Reset
31:30	SCHEME	PID Scheme: Used to distinguish between old ID scheme and current. Spare bit to encode future schemes EDMA uses new scheme, indicated with value of 0x1.	R	0x1
29:28	Reserved	Read returns 0.	R	0x0
27:16	FUNC	Function indicates a software compatible module family.	R	0x001
15:11	RTL	RTL Version	R	0x--
10:8	MAJOR	Major Revision	R	0x3
7:6	CUSTOM	Custom revision field: Not used on this version of EDMA.	R	0x0
5:0	MINOR	Minor Revision	R	0x--

### 1.5.6.2 TPCC\_CCCFG

**Table 1-107. TPCC\_CCCFG**

<b>Address Offset</b>	0x0004																																
<b>Physical address</b>	0x01C0 0004								<b>Instance</b>	IVA2.2 TPCC																							
<b>Description</b>	CC Configuration Register																																
<b>Type</b>	R																																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reserved						MPEXIST	CHMAPEXIST	Reserved	NUMREGN			Reserved	NUMTC			Reserved	NUMPAENTRY			Reserved	NUMINTCH			Reserved	NUMQDMACH			Reserved	NUMDMACH				
<b>Bits</b>		<b>Field Name</b>										<b>Description</b>										<b>Type</b>				<b>Reset</b>							
31:26		Reserved										Read returns 0.										R				0x00							
25		MPEXIST										Memory Protection Existence MPEXIST = 0: No memory protection. MPEXIST = 1: Memory Protection logic included.										R				1							
24		CHMAPEXIST										Channel Mapping Existence CHMAPEXIST = 0: No Channel mapping. CHMAPEXIST = 1: Channel mapping logic included.										R				1							
23:22		Reserved										Read returns 0.										R				0x0							
21:20		NUMREGN										Number of MP and Shadow regions  Read 0x0:           0 Regions Read 0x1:           2 Regions Read 0x2:           4 Regions Read 0x3:           8 Regions										R				0x3							
19		Reserved										Read returns 0.										R				0							
18:16		NUMTC										Number of Queues/Number of TCs  Read 0x0:           1 TC/Event Queue Read 0x1:           2 TC/Event Queue Read 0x2:           3 TC/Event Queue Read 0x3:           4 TC/Event Queue Read 0x4:           5 TC/Event Queue Read 0x5:           6 TC/Event Queue Read 0x6:           7 TC/Event Queue Read 0x7:           8 TC/Event Queue										R				0x1							
15		Reserved										Read returns 0.										R				0							
14:12		NUMPAENTRY										Number of PaRAM entries  Read 0x0:           16 entries Read 0x1:           32 entries (unsupported setting) Read 0x2:           64 entries Read 0x3:           128 entries Read 0x4:           256 entries Read 0x5:           512 entries										R				0x3							
11		Reserved										Read returns 0.										R				0							
10:8		NUMINTCH										Number of Interrupt Channels  Read 0x1:           8 Interrupt channels Read 0x2:           16 Interrupt channels Read 0x3:           32 Interrupt channels Read 0x4:           64 Interrupt channels										R				0x4							
7		Reserved										Read returns 0.										R				0							
6:4		NUMQDMACH										Number of QDMA Channels										R				0x2							

**IVA2.2 Subsystem Registers**
[www.ti.com](http://www.ti.com)

Bits	Field Name	Description	Type	Reset
		Read 0x0: No QDMA Channels		
		Read 0x1: 2 QDMA Channels		
		Read 0x2: 4 QDMA Channels		
		Read 0x3: 6 QDMA Channels		
		Read 0x4: 8 QDMA Channels		
3	Reserved	Read returns 0.	R	0
2:0	NUMDMACH	Number of DMA Channels	R	0x5
		Read 0x0: No DMA Channels		
		Read 0x1: 4 DMA Channels		
		Read 0x2: 8 DMA Channels		
		Read 0x3: 16 DMA Channels		
		Read 0x4: 32 DMA Channels		
		Read 0x5: 64 DMA Channels		

### 1.5.6.3 TPCC\_CLKGDIS

**Table 1-108. TPCC\_CLKGDIS**

Address Offset	0x00FC																															
Physical address	0x01C0 00FC								Instance								IVA2.2 TPCC															
Description	Auto Clock Gate Disable																															
Type	RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																															CLKGDIS	
Bits		Field Name										Description										Type		Reset								
31:1		Reserved										Write 0s for future compatibility. Read returns 0.										RW		0x00000000								
0		CLKGDIS										Auto Clock Gate Disable										RW		0								

### 1.5.6.4 TPCC\_DCHMAPi

**Table 1-109. TPCC\_DCHMAPi**

<b>Address Offset</b>	0x0100 + (0x4*i)																<b>Instance</b>	IVA2.2 TPCC															
<b>Physical address</b>	0x01C0 0100 + (0x4*i)																																
<b>Description</b>	DMA Channel i Mapping Register																																
<b>Type</b>	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																PAENTRY								Reserved							

Bits	Field Name	Description	Type	Reset
31:14	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00000
13:5	PAENTRY	PaRAM Entry number for DMA Channel i.	RW	0x000
4:0	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00

### 1.5.6.6 TPCC\_DMAQNUM0

**Table 1-111. TPCC\_DMAQNUM0**

Address Offset		0x0240																																	
Physical address		0x01C0 0240																Instance		IVA2.2 TPCC															
Description		DMA Queue Number Register 0 Contains the Event queue number to be used for the corresponding DMA Channel.																																	
Type		RW																																	
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 1.5.6.23 TPCC\_CCERR

**Table 1-128. TPCC\_CCERR**

<b>Address Offset</b>	0x0318	<b>Instance</b>	IVA2.2 TPCC
<b>Physical address</b>	0x01C0 0318		
<b>Description</b>	CC Error Register		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
Reserved																TCERR	Reserved																QTHRXCD1	QTHRXCD0

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Read returns 0.	R	0x0000
16	TCERR	Transfer Completion Code Error: TCCERR = 0: Total number of allowed TCCs outstanding has not been reached. TCCERR = 1: Total number of allowed TCCs has been reached. TCCERR can be cleared by writing 1 to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors were previously clear), then an error will be signaled with TPCC error interrupt.	R	0
15:2	Reserved	Read returns 0.	R	0x00
1	QTHRXCD1	Queue Threshold Error for Q1: QTHRXCD1 = 0: Watermark/threshold has not been exceeded. QTHRXCD1 = 1: Watermark/threshold has been exceeded. CCERR.QTHRXCD1 can be cleared by writing 1 to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0
0	QTHRXCD0	Queue Threshold Error for Q0: QTHRXCD0 = 0: Watermark/threshold has not been exceeded. QTHRXCD0 = 1: Watermark/threshold has been exceeded. CCERR.QTHRXCD0 can be cleared by writing 1 to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0

### 1.5.6.24 TPCC\_CCERRCLR

**Table 1-129. TPCC\_CCERRCLR**

<b>Address Offset</b>	0x031C																																<b>Instance</b>	IVA2.2 TPCC															
<b>Physical address</b>	0x01C0 031C																																																
<b>Description</b>	CC Error Clear Register																																																
<b>Type</b>	W																																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
Reserved																TCERR	Reserved																QTHRXC1	QTHRXC0

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Write 0s for future compatibility.	W	0x0000
16	TCERR	Clear Error for CCERR.TCERR: Write of 1 clears the value of CCERR bit N. Writes of 0 have no effect.	W	0
15:2	Reserved	Write 0s for future compatibility.	W	0x00
1	QTHRXC1	Clear error for CCERR.QTHRXC1: Write of 1 clears the values of QSTAT1.WM, QSTAT1.THRXCD, CCERR.QTHRXC1 Writes of 0 have no effect.	W	0
0	QTHRXC0	Clear error for CCERR.QTHRXC0: Write of 1 clears the values of QSTAT0.WM, QSTAT0.THRXCD, CCERR.QTHRXC0 Writes of 0 have no effect.	W	0

### 1.5.6.25 TPCC\_EEVAL

**Table 1-130. TPCC\_EEVAL**

<b>Address Offset</b>	0x0320																																
<b>Physical address</b>	0x01C0 0320																<b>Instance</b>	IVA2.2 TPCC															
<b>Description</b>	Error Eval Register																																
<b>Type</b>	W																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reserved																																SET	EVAL

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility.	W	0x00000000
1	SET	Error Interrupt Set: CPU write of 1 to the SET bit causes the TPCC error interrupt to be pulsed regardless of state of EMR/EMRH, QEMR, or CCERR. CPU write of 0 has no effect.	W	0
0	EVAL	Error Interrupt Evaluate: CPU write of 1 to the EVAL bit causes the TPCC error interrupt to be pulsed if any errors have not been cleared in the EMR/EMRH, QEMR, or CCERR registers. CPU write of 0 has no effect.	W	0

### 1.5.6.26 TPCC\_DRAEj

**Table 1-131. TPCC\_DRAEj**

<b>Address Offset</b>	0x0340 + (0x8*i)				
<b>Physical address</b>	0x01C0 0340 + (0x8*i)			<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	DMA Region Access enable for bit N in Region i: En = 0: Accesses through Region i address space to Bit N in any DMA Channel Register are not allowed. Reads will return b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region i interrupt. En = 1: Accesses through Region i address space to Bit N in any DMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region i interrupt.

17	QUEACTV1	Queue 1 Active QUEACTV1 = 0: No Evts are queued in Q1. QUEACTV1 = 1: At least one TR is queued in Q1.	R	0
16	QUEACTV0	Queue 0 Active QUEACTV0 = 0: No Evts are queued in Q0. QUEACTV0 = 1: At least one TR is queued in Q0.	R	0
15:14	Reserved	Read returns 0.	R	0x0
13:8	COMPACTV	Completion Request Active: Counter that tracks the total number of completion requests submitted to the TC. The counter increments when a TR is submitted with TCINTEN or TCCHEN set to 1. The counter decrements for every valid completion code received from any of the external TCs. The CC will not service new TRs if COMPACTV count is already at the limit. COMPACTV = 0: No completion requests outstanding. COMPACTV = 1: Total of 1 completion request outstanding. ... COMPACTV = 63 : Total of 63 completion requests are outstanding. No additional TRs will be submitted until count is less than 63.	R	0x00
7:5	Reserved	Read returns 0.	R	0x0

Bits	Field Name	Description	Type	Reset
4	ACTV	Channel Controller Active: Channel Controller Active is a logical-OR of each of the *ACTV signals. The ACTV bit must remain high through the life of a TR. ACTV = 0: Channel is idle. ACTV = 1: Channel is busy.	R	0
3	Reserved	Read returns 0.	R	0
2	TRACTV	Transfer Request Active: TRACTV = 0: Transfer Request processing/submission logic is inactive. TRACTV = 1: Transfer Request processing/submission logic is active.	R	0
1	QEV TACTV	QDMA Event Active: QEV TACTV = 0: No enabled QDMA Events are active within the CC. QEV TACTV = 1: At least one enabled DMA Event(ER & EER, ESR, CER) is active within the CC.	R	0
0	EVTACTV	DMA Event Active: EVTACTV = 0: No enabled DMA Events are active within the CC. EVTACTV = 1: At least one enabled DMA Event(ER & EER, ESR, CER) is active within the CC.	R	0

### 1.5.6.39 TPCC\_ER

**Table 1-144. TPCC\_ER**

<b>Address Offset</b>	0x1000	<b>Instance</b>	IVA2.2 TPCC
<b>Physical address</b>	0x01C0 1000		
<b>Description</b>	Event Register: If EMR.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.		
<b>Type</b>	R

### 1.5.6.44 TPCC\_CER

**Table 1-149. TPCC\_CER**

Address Offset	0x1018																																																																																															
Physical address	0x01C0 1018								Instance								IVA2.2 TPCC																																																																															
Description	<div>Chained Event Register:</div> <div>If CER.En bit is set (regardless of state of EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared through software.</div>

### 1.5.6.46 TPCC\_EER

**Table 1-151. TPCC\_EER**

Address Offset	0x1020																																																																																														
Physical address	0x01C0 1020								Instance	IVA2.2 TPCC																																																																																					
Description	<p>Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.</p>

### 1.5.6.63 TPCC\_IEVAL

**Table 1-168. TPCC\_IEVAL**

<b>Address Offset</b>	0x1078	<b>Instance</b>	IVA2.2 TPCC
<b>Physical address</b>	0x01C0 1078		
<b>Description</b>	Interrupt Eval Register		
<b>Type</b>	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																SET		EVAL													

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility.	W	0x00000000
1	SET	Interrupt Set: CPU write of 1 to the SETn bit causes the tpcc_intN output signal to be pulsed regardless of state of interrupts enable (IERn) and status (IPRn). CPU write of 0 has no effect.	W	0
0	EVAL	Interrupt Evaluate: CPU write of 1 to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (IPRn). CPU write of 0 has no effect.	W	0

### 1.5.6.64 TPCC\_QER

**Table 1-169. TPCC\_QER**

<b>Address Offset</b>	0x1080	<b>Instance</b>	IVA2.2 TPCC
<b>Physical address</b>	0x01C0 1080		
<b>Description</b>	QDMA Event Register: If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 1.5.6.70 TPCC\_ER\_Rn

**Table 1-175. TPCC\_ER\_Rn**

Address Offset	0x2000-0x2E00 in 0x200 byte increments																																																																																														
Physical address	0x01C0 2000-0x01C0 2E00															Instance	IVA2.2 TPCC																																																																														
Description	Event Register: If ER.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.

### 1.5.6.76 TPCC\_CERH\_Rn

**Table 1-181. TPCC\_CERH\_Rn**

Address Offset	0x201C-0x2E1C in 0x200 byte increments																																																																																															
Physical address	0x01C0 201C-0x01C0 2E1C																Instance	IVA2.2 TPCC																																																																														
Description	Chained Event Register (High Part): If CERH.En bit is set (regardless of state of EERH.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CERH.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CERH.En bit is cleared when the corresponding event is prioritized and serviced. If the CERH.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CERH.En cannot be set or cleared through software.

### 1.5.6.77 TPCC\_EER\_Rn

**Table 1-182. TPCC\_EER\_Rn**

Address Offset	0x2020-0x2E20 in 0x200 byte increments																																																																																														
Physical address	0x01C0 2020-0x01C0 2E20																Instance	IVA2.2 TPCC																																																																													
Description	<p>Event Enable Register:</p> <p>Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register.</p> <p>EER.En = 0: ER.En is not enabled to trigger DMA transfers.</p> <p>EER.En = 1: ER.En is enabled to trigger DMA transfers.</p>

<b>Bits</b>	<b>Field Name</b>		<b>Description</b>																<b>Type</b>		<b>Reset</b>												
31:2	Reserved		Write 0s for future compatibility.																W		0x00000000												
1	SET		Interrupt Set: CPU write of 1 to the SETn bit causes the tpcc_intN output signal to be pulsed regardless of state of interrupts enable (IERn) and status (IPRn). CPU write of 0 has no effect.																W		0												
0	EVAL		Interrupt Evaluate: CPU write of 1 to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (IPRn). CPU write of 0 has no effect.																W		0												

### 1.5.6.95 TPCC\_QER\_Rn

**Table 1-200. TPCC\_QER\_Rn**

<b>Address Offset</b>	0x2080-0x2E80 in 0x200 byte increments																		
<b>Physical address</b>	0x01C0 2080-0x01C0 2E80								<b>Instance</b>	IVA2.2 TPCC									
<b>Description</b>	QDMA Event Register: If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.																		
<b>Type</b>	R																		
<div><div>3130292827262524</div><div>2322212019181716</div><div>15141312111098</div><div>76543210</div></div>

<b>Bits</b>		<b>Field Name</b>				<b>Description</b>																<b>Type</b>				<b>Reset</b>						
31		PRIV				Privilege level: Privilege level (supervisor vs. user) for the host/cpu/dma that programmed this PaRAM Entry. Value is set with the vbus priv value when any part of the PaRAM Entry is written. Not writeable through vbus wdata bus. Is readable through VBus rdata bus. PRIV = 0: User level privilege PRIV = 1: Supervisor level privilege																R				-						
30		SECURE				Secure level: Secure level for the host/cpu/dma that programmed this PaRAM Entry. Value is set with the vbus secure value when any part of the PaRAM Entry is written. Not writeable through vbus wdata bus. Is readable through VBus rdata bus. SECURE = 0: Normal access SECURE = 1: Secure access																R				-						
29:27		Reserved				Write 0s for future compatibility. Read returns 0.																RW				0x-						
26:24		PRIVID				Privilege ID: Privilege ID for the external host/cpu/dma that programmed this PaRAM Entry. This value is set with the vbus privid value when any part of the PaRAM Entry is written. Not writeable through vbus wdata bus. Is readable through VBus rdata bus.																R				0x-						
23		ITCCHEN				Intermediate transfer completion chaining enable: 0: Intermediate transfer complete chaining is disabled. 1: Intermediate transfer complete chaining is enabled.																RW				-						
22		TCCHEN				Transfer complete chaining enable: 0: Transfer complete chaining is disabled. 1: Transfer complete chaining is enabled.																RW				-						
21		ITCINTEN				Intermediate transfer completion interrupt enable: 0: Intermediate transfer complete interrupt is disabled. 1: Intermediate transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)																RW				-						
20		TCINTEN				Transfer complete interrupt enable: 0: Transfer complete interrupt is disabled. 1: Transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)																RW				-						
19		WIMODE				Backward compatibility mode: 0: Normal operation 1: WI Backwards Compatibility mode, forces BCNT to be adjusted by 1 upon TR submission (0 means 1, 1 means 2, ... ) and forces ACNT to be treated as a word-count (left shifted by 2 by hardware to create byte cnt for TR submission)																RW				-						
18		Reserved				Write 0s for future compatibility. Read returns 0.																RW				-						

Bits	Field Name	Description	Type	Reset
17:12	TCC	Transfer Complete Code: The 6-bit code is used to set the relevant bit in CER (bit CER[TCC]) for chaining or in IER (bit IER[TCC]) for interrupts.	RW	0x--
11	TCCMODE	Transfer complete code mode: Indicates the point at which a transfer is considered completed. Applies to both chaining and interrupt. 0: Normal Completion, A transfer is considered completed after the transfer parameters are returned to the CC from the TC (which was returned from the peripheral). 1: Early Completion, A transfer is considered completed after the CC submits a TR to the TC. CC generates completion code internally .	RW	-
10:8	FWID	FIFO width: Applies if either SAM or DAM is set to FIFO mode. Pass-thru to TC.  0x0: FIFO width is 8-bit 0x1: FIFO width is 16-bit 0x2: FIFO width is 32-bit 0x3: FIFO width is 64-bit 0x4: FIFO width is 128-bit 0x5: FIFO width is 256-bit	RW	0x-
7:4	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x-
3	STATIC	Static Entry: 0: Entry is updated as normal 1: Entry is static, Count and Address updates are not updated after TRP is submitted. Linking is not performed.	RW	-
2	SYNCDIM	Transfer Synchronization Dimension: 0: A-Sync, Each event triggers the transfer of ACNT elements. 1: AB-Sync, Each event triggers the transfer of BCNT arrays of ACNT elements	RW	-
1	DAM	Destination Address Mode: Destination Address Mode within an array. Pass-thru to TC. 0: INCR, Dst addressing within an array increments. Dst is not a FIFO. 1: FIFO, Dst addressing within an array wraps around upon reaching FIFO width.	RW	-
0	SAM	Source Address Mode: Source Address Mode within an array. Pass-thru to TC. 0: INCR, Src addressing within an array increments. Source is not a FIFO. 1: FIFO, Src addressing within an array wraps around upon reaching FIFO width.	RW	-

SRC																																
<b>Bits</b>	<b>Field Name</b>							<b>Description</b>																<b>Type</b>	<b>Reset</b>							
31:0	SRC							Source Address: The 32-bit source address parameters specify the starting byte address of the source. If SAM is set to FIFO mode then the user should program the Source address to be aligned to the value specified by the OPT.FWID field. No errors are recognized here but TC will assert error if this is not true.																RW	0x-----							

### 1.5.6.103 TPCC\_ABCNTm

**Table 1-208. TPCC\_ABCNTm**

<b>Address Offset</b>	0x4008 + (0x20*i)																<b>Instance</b>	IVA2.2 TPCC													
<b>Physical address</b>	0x01C0 4008 + (0x20*i)																														
<b>Description</b>	A and B byte count																														
<b>Type</b>	RW																														

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	<p>BCNT : Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame.</p> <p>In normal mode, a BCNT of 0 is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field.</p> <p>If the OPTi.WIMODE bit is set, then the programmed BCNT value will be incremented by 1 before submission to TC. I.e., 0 means 1, 1 means 2, 2 means 3, ..., 0xFFFE means 0xFFFF. A value of 0xFFFF is an illegal value that will be treated as a Null TR.</p>	RW	0x----
15:0	ACNT	<p>ACNT : number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to TC. An ACNT of 0 is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field.</p> <p>If the OPTi.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are Reserved and should always be written as b00 by the user. If user writes a value other than 0, it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition, the ACNT definition will disregard the 2 msbits. I.e., a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer, resulting in null or dummy operation dependent on the state of BCNT and CCNT.</p>	RW	0x----

#### 1.5.6.104 TPCC\_DSTm

DBIDX																SBIDX																		
<b>Bits</b>	<b>Field Name</b>																<b>Description</b>																<b>Type</b>	<b>Reset</b>
31:16	DBIDX																Destination 2nd Dimension Index: DBIDX is a 16-bit signed value (2s complement) used for destination address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-Sync and AB-Sync transfers.																RW	0x----
15:0	SBIDX																Source 2nd Dimension Index: SBIDX is a 16-bit signed value (2s complement) used for source address modification in between each array in the 2nd dimension. It is a signed value between - 32768 and 32767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-sync and AB-sync transfers.																RW	0x----

### 1.5.6.106 TPCC\_LNKm

**Table 1-211. TPCC\_LNKm**

<b>Address Offset</b>	0x4014 + (0x20*i)																<b>Instance</b>	IVA2.2 TPCC															
<b>Physical address</b>	0x01C0 4014 + (0x20*i)																																
<b>Description</b>	Link and Reload parameters																																
<b>Type</b>	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Synced transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not CC-thus BCNTRLD is a don't care field.	RW	0x----
15:0	LINK	Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to 0) with a new PaRAM Entry. This is called linking. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the literal byte address of the LINK parameter or the PaRAM base-relative address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., don't have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Link and all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid/Secure state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NULL PaRAM link field.	RW	0x----

### 1.5.6.107 TPCC\_CIDXm

**Table 1-212. TPCC\_CIDXm**

<b>Address Offset</b>	0x4018 + (0x20*i)																<b>Instance</b>	IVA2.2 TPCC															
<b>Physical address</b>	0x01C0 4018 + (0x20*i)																																
<b>Description</b>																																	
<b>Type</b>		RW

### 1.5.6.108 TPCC\_CCNT

**Table 1-213. TPCC\_CCNT**

<b>Address Offset</b>	0x401C + (0x20*i)																<b>Instance</b>	IVA2.2 TPCC															
<b>Physical address</b>	0x01C0 401C + (0x20*i)																																
<b>Description</b>	C byte count																																
<b>Type</b>	RW																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																CCNT															

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
15:0	CCNT	CCNT Count for 3rd Dimension: CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT can be anywhere between 1 and 65535. Therefore, the maximum number of frames in a block is 65535 (64K-1 frames). CCNT of 1 means 1 frame in the block, and CCNT of 0 means 0 frames in the block. A CCNT value of 0 is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPTi field. WIMODE has no affect on CCNT operation.	RW	0x----

## 1.5.7 TPTC0 and TPTC1 Register Descriptions

This section provides information about the TPTC0 and TPTC1 Modules. Each register in the Modules is described separately below.

### 1.5.7.1 TPTCj\_PID

**Table 1-214. TPTCj\_PID**

<b>Address Offset</b>	0x000																																
<b>Physical address</b>	0x01C1 0000																<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 0400																<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	Peripheral ID Register																																
<b>Type</b>	R																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SCHEME		Reserved		FUNC												RTL				MAJOR			CUSTOM		MINOR						

Bits	Field Name	Description	Type	Reset
31:30	SCHEME	PID Scheme: Used to distinguish between old ID scheme and current. Spare bit to encode future schemes EDMA uses new scheme, indicated with value of 0x1.	RW	0x1
29:28	Reserved	Read returns 0.	R	0x0
27:16	FUNC	Function indicates a software compatible module family.	RW	0x000
15:11	RTL	RTL Version	RW	0x--
10:8	MAJOR	Major Revision	RW	0x3
7:6	CUSTOM	Custom revision field: Not used on this version of EDMA.	RW	0x0
5:0	MINOR	Minor Revision	RW	0x--

### 1.5.7.2 TPTCj\_TCCFG

**Table 1-215. TPTCj\_TCCFG**

<b>Address Offset</b>	0x004																															
<b>Physical address</b>	0x01C1 0004															<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 0404															<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	TC Configuration Register																															
<b>Type</b>	R																															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																					DREGDEPTH	Reserved	BUSWIDTH	Reserved	FIFOSIZE						

Bits	Field Name	Description	Type	Reset
31:10	Reserved	Read returns 0.	R	0x000000
9:8	DREGDEPTH	Dst Register FIFO Depth Parameterization	R	0x- <sup>(1)</sup>
		Read 0x0: 1 entry		
		Read 0x1: 2 entries		
		Read 0x2: 4 entries		
7:6	Reserved	Read returns 0.	R	0x0
5:4	BUSWIDTH	Bus Width Parameterization	R	0x1
		Read 0x0: 32-bit		
		Read 0x1: 64-bit		
		Read 0x2: 128-bit		
3	Reserved	Read returns 0.	R	0
2:0	FIFOSIZE	Fifo Size Parameterization	R	0x- <sup>(1)</sup>
		Read 0x0: 32 byte FIFO		
		Read 0x1: 64 byte FIFO		
		Read 0x2: 128 byte FIFO		
		Read 0x3: 256 byte FIFO		
		Read 0x4: 512 byte FIFO		

(1) Depends on the hardware parameters of TPTC0 and TPTC1.

### 1.5.7.3 TPTCj\_TCSTAT

**Table 1-216. TPTCj\_TCSTAT**

<b>Address Offset</b>	0x100		
<b>Physical address</b>	0x01C1 0100	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0500	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	TC Status Register		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																DFSTRTPTR		Reserved		ACTV	Reserved	DSTACTV		Reserved	WSACTV	SRCACTV	PROGBUSY				

Bits	Field Name	Description	Type	Reset
31:14	Reserved	Read returns 0.	R	0x00000
13:12	DFSTRTPTR	Dst FIFO Start Pointer Represents the offset to the head entry of Dst Register FIFO, in units of *entries*. Legal values = 0x0 to 0x3	R	0x0
11:9	Reserved	Read returns 0.	R	0x0
8	ACTV	Channel Active Channel Active is a logical-OR of each of the *BUSY/ACTV signals. The ACTV bit must remain high through the life of a TR. ACTV = 0: Channel is idle. ACTV = 1: Channel is busy.	R	1
7	Reserved	Read returns 0.	R	0
6:4	DSTACTV	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter.  Read 0x0: FIFO set is empty. Read 0x1: Dst FIFO contains 1 TR  Read 0x2: Dst FIFO contains 2 TR  Read 0x3: Dst FIFO contains 3 TR  Read 0x4: Dst FIFO contains 4 TR	R	0x0
3	Reserved	Read returns 0.	R	0
2	WSACTV	Write Status Active WSACTV = 0: Write status is not pending. Write status has been received for all previously issued write commands. WSACTV = 1: Write Status is pending. Write status has not been received for all previously issued write commands.	R	0
1	SRCACTV	Source Active State SRCACTV = 0: Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full (DSTFULL == 1). SRCACTV = 1: Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.	R	0

Bits	Field Name	Description	Type	Reset
0	PROGBUSY	Program Register Set Busy PROGBUSY = 0: Prog set idle and is available for programming. PROGBUSY = 1: Prog set busy. User should poll for PROGBUSY equal to 0 prior to reprogramming the Program Register set.	R	0

### 1.5.7.5 TPTCj\_INTEN

**Table 1-218. TPTCj\_INTEN**

<b>Address Offset</b>	0x108		
<b>Physical address</b>	0x01C1 0108	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0508	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Interrupt Enable Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																TRDONE		PROGEMPTY													

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00000000
1	TRDONE	TR Done Event Enable: INTEN.TRDONE = 0: TRDONE Event is disabled. INTEN.TRDONE = 1: TRDONE Event is enabled, and contributes to interrupt generation	RW	0
0	PROGEMPTY	Program Set Empty Event Enable: INTEN.PROGEMPTY = 0: PROGEMPTY Event is disabled. INTEN.PROGEMPTY = 1: PROGEMPTY Event is enabled, and contributes to interrupt generation	RW	0

#### 1.5.7.6 TPTCj\_INTCLR

**Table 1-219. TPTCj\_INTCLR**

<b>Address Offset</b>	0x10C																																
<b>Physical address</b>	0x01C1 010C																<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 050C																<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	Interrupt Clear Register																																
<b>Type</b>	W																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reserved																																TRDONE	PROGEMPTY

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility.	W	0x00000000
1	TRDONE	TR Done Event Clear: INTCLR.TRDONE = 0: Writes of 0 have no effect. INTCLR.TRDONE = 1: Write of 1 clears INTSTAT.TRDONE bit	W	0
0	PROGEMPTY	Program Set Empty Event Clear: INTCLR.PROGEMPTY = 0: Writes of 0 have no effect. INTCLR.PROGEMPTY = 1: Write of 1 clears INTSTAT.PROGEMPTY bit	W	0

#### 1.5.7.7 TPTCj\_INTCMD`

**Table 1-220. TPTCj\_INTCMD**

<b>Address Offset</b>	0x110		
<b>Physical address</b>	0x01C1 0110	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0510	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Interrupt Command Register		
<b>Type</b>	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																															SET	EVAL

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility.	W	0x00000000
1	SET	Set TPTC interrupt: Write of 1 to SET causes TPTC interrupt to be pulsed unconditionally. Writes of 0 have no effect.	W	0
0	EVAL	Evaluate state of TPTC interrupt Write of 1 to EVAL causes TPTC interrupt to be pulsed if any of the INTSTAT bits are set to 1. Writes of 0 have no effect.	W	0

### 1.5.7.8 TPTCj\_ERRSTAT

**Table 1-221. TPTCj\_ERRSTAT**

<b>Address Offset</b>	0x120																																
<b>Physical address</b>	0x01C1 0120																<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 0520																<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	Error Status Register																																
<b>Type</b>	R																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																												MMRAERR	TRERR	Reserved	BUSERR

Bits	Field Name	Description	Type	Reset
31:4	Reserved	Read returns 0.	R	0x00000000
3	MMRAERR	MMR Address Error: MMRAERR = 0: Condition not detected. MMRAERR = 1: User attempted to read or write to invalid address configuration memory map. (Is only be set for nonemulation accesses). No additional error information is recorded.	R	0
2	TRERR	TR Error: TR detected that violates FIFO Mode transfer (SAM or DAM is 1) alignment rules or has ACNT or BCNT == 0. No additional error information is recorded.	R	0
1	Reserved	Read returns 0.	R	0
0	BUSERR	Bus Error Event: BUSERR = 0: Condition not detected. BUSERR = 1: TC has detected an error code on the write response bus or read response bus. Error information is stored in Error Details Register (ERRDET).	R	0

#### 1.5.7.9 TPTCj\_ERREN

**Table 1-222. TPTCj\_ERREN**

<b>Address Offset</b>	0x124		
<b>Physical address</b>	0x01C1 0124	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0524	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Error Enable Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																												MMRAERR	TRERR	Reserved	BUSERR

Bits	Field Name	Description	Type	Reset
31:4	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000000
3	MMRAERR	Interrupt enable for ERRSTAT.MMRAERR: ERREN.MMRAERR = 0: BUSERR is disabled. ERREN.MMRAERR = 1: MMRAERR is enabled, and contributes to the TPTC error interrupt generation.	RW	0
2	TRERR	Interrupt enable for ERRSTAT.TRERR: ERREN.TRERR = 0: BUSERR is disabled. ERREN.TRERR = 1: TRERR is enabled, and contributes to the TPTC error interrupt generation.	RW	0
1	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0
0	BUSERR	Interrupt enable for ERRSTAT.BUSERR: ERREN.BUSERR = 0: BUSERR is disabled. ERREN.BUSERR = 1: BUSERR is enabled, and contributes to the TPTC error interrupt generation.	RW	0

### 1.5.7.10 TPTCj\_ERRCLR

**Table 1-223. TPTCj\_ERRCLR**

<b>Address Offset</b>	0x128

Bits	Field Name	Description	Type	Reset
31:4	Reserved	Write 0s for future compatibility.	W	0x00000000
3	MMRAERR	Interrupt clear for ERRSTAT.MMRAERR: ERRCLR.MMRAERR = 0: Writes of 0 have no effect. ERRCLR.MMRAERR = 1: Write of 1 clears ERRSTAT.MMRAERR bit. Write of 1 to ERRCLR.MMRAERR does not clear the ERRDET register.	W	0
2	TRERR	Interrupt clear for ERRSTAT.TRERR: ERRCLR.TRERR = 0: Writes of 0 have no effect. ERRCLR.TRERR = 1: Write of 1 clears ERRSTAT.TRERR bit. Write of 1 to ERRCLR.TRERR does not clear the ERRDET register.	W	0
1	Reserved	Write 0s for future compatibility.	W	0
0	BUSERR	Interrupt clear for ERRSTAT.BUSERR: ERRCLR.BUSERR = 0: Writes of 0 have no effect. ERRCLR.BUSERR = 1: Write of 1 clears ERRSTAT.BUSERR bit. Write of 1 to ERRCLR.BUSERR clears the ERRDET register.	W	0

#### 1.5.7.11 TPTCj\_ERRDET

**Table 1-224. TPTCj\_ERRDET**

<b>Address Offset</b>	0x12C		
<b>Physical address</b>	0x01C1 012C	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 052C	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Error Details Register		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														TCCCHEN	TTCINTEN	Reserved	TCC						Reserved				STAT				

Bits	Field Name	Description	Type	Reset																						
31:18	Reserved	Read returns 0.	R	0x0000																						
17	TCCHEN	Contains the OPT.TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0																						
16	TCINTEN	Contains the OPT.TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0																						
15:14	Reserved	Read returns 0.	R	0x0																						
13:8	TCC	Transfer Complete Code: Contains the OPT.TCC value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x00																						
7:4	Reserved	Read returns 0.	R	0x0																						
3:0	STAT	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle, then the TC chooses non-zero version. If both are non-zero then write status is treated as higher priority. Encoding of errors matches the CBA spec and is summarized here: 0xF = <table><tr><td>Read 0x0:</td><td>No Error (should not cause error to be latched)</td></tr><tr><td>Read 0x1:</td><td>Read Addressing error</td></tr><tr><td>Read 0x2:</td><td>Read Privilege error</td></tr><tr><td>Read 0x3:</td><td>Read Timeout error</td></tr><tr><td>Read 0x4:</td><td>Read Data error</td></tr><tr><td>Read 0x7:</td><td>Read Exclusive-operation failure</td></tr><tr><td>Read 0x8:</td><td>No Error (should not cause error to be latched)</td></tr><tr><td>Read 0x9:</td><td>Write Addressing error</td></tr><tr><td>Read 0xA:</td><td>Write Privilege error</td></tr><tr><td>Read 0xB:</td><td>Write Timeout error</td></tr><tr><td>Read 0xC:</td><td>Write Data error</td></tr></table>	Read 0x0:	No Error (should not cause error to be latched)	Read 0x1:	Read Addressing error	Read 0x2:	Read Privilege error	Read 0x3:	Read Timeout error	Read 0x4:	Read Data error	Read 0x7:	Read Exclusive-operation failure	Read 0x8:	No Error (should not cause error to be latched)	Read 0x9:	Write Addressing error	Read 0xA:	Write Privilege error	Read 0xB:	Write Timeout error	Read 0xC:	Write Data error	R	0x0
Read 0x0:	No Error (should not cause error to be latched)																									
Read 0x1:	Read Addressing error																									
Read 0x2:	Read Privilege error																									
Read 0x3:	Read Timeout error																									
Read 0x4:	Read Data error																									
Read 0x7:	Read Exclusive-operation failure																									
Read 0x8:	No Error (should not cause error to be latched)																									
Read 0x9:	Write Addressing error																									
Read 0xA:	Write Privilege error																									
Read 0xB:	Write Timeout error																									
Read 0xC:	Write Data error																									

Bits	Field Name	Description	Type	Reset
		Read 0xF:	Write Exclusive-operation failure	

#### 1.5.7.12 TPTCj\_ERRCMD

**Table 1-225. TPTCj\_ERRCMD**

<b>Address Offset</b>	0x130																																
<b>Physical address</b>	0x01C1 0130																<b>Instance</b>	IVA2.2 TPTC0

<b>Description</b>	rsvd, return 0x0 w/o AERROR		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DADDR																															

Bits	Field Name	Description	Type	Reset
31:0	DADDR	Destination address is not applicable for Src Active Register Set. Reads return 0x0	R	0x00000000

### 1.5.7.24 TPTCj\_SABIDX

**Table 1-237. TPTCj\_SABIDX**

<b>Address Offset</b>	0x250		
<b>Physical address</b>	0x01C1 0250	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0650	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Src Actv Set B-Dim Idx		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBIDX																SBIDX															

Bits	Field Name	Description	Type	Reset
31:16	DBIDX	Dest B-Idx for Source Active Register Set. Value copied from PBIDX: B-Idx offset between Destination arrays: Represents the offset in bytes between the starting address of each destination array (recall that there are BCNT arrays of ACNT elements). DBIDX is always used, regardless of whether DAM is Increment or FIFO mode.	R	0x0000
15:0	SBIDX	Source B-Idx for Source Active Register Set. Value copied from PBIDX: B-Idx offset between Source arrays: Represents the offset in bytes between the starting address of each source array (recall that there are BCNT arrays of ACNT elements). SBIDX is always used, regardless of whether SAM is Increment or FIFO mode.	R	0x0000

### 1.5.7.25 TPTCj\_SAMPPRXY

**Table 1-238. TPTCj\_SAMPPRXY**

<b>Address Offset</b>	0x254																																
<b>Physical address</b>	0x01C1 0254																<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 0654																<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	Src Actv Set Mem Protect Proxy																																
<b>Type</b>	R																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																						SECURE	PRIV	Reserved				PRIVID			

Bits	Field Name	Description	Type	Reset
31:10	Reserved	Read returns 0.	R	0x000000
9	SECURE	Secure Level: SECURE = 0: Nonsecure access SECURE = 1: Secure access SAMPPRXY.SECURE is always updated with the value from the configuration bus secure field on any/every write to Program Set BIDX Register (trigger register). The SECURE value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The secure attribute is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection and security checks based on the SECURE level of the external host that sets up the DMA transaction.	R	0
8	PRIV	Privilege Level: PRIV = 0: User level privilege PRIV = 1: Supervisor level privilege SAMPPRXY.PRIV is always updated with the value from the configuration bus Privilege field on any/every write to Program Set BIDX Register (trigger register). The PRIV value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the PRIV of the external host that sets up the DMA transaction.	R	0
7:4	Reserved	Read returns 0.	R	0x0
3:0	PRIVID	Privilege ID: SAMPPRXY.PRIVID is always updated with the value from configuration bus Privilege ID field on any/every write to Program Set BIDX Register (trigger register). The PRIVID value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the privid of the external host that sets up the DMA transaction.	R	0x0

### 1.5.7.26 TPTCj\_SACNTRLD

**Table 1-239. TPTCj\_SACNTRLD**

<b>Address Offset</b>	0x258		
<b>Physical address</b>	0x01C1 0258	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0658	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Src Actv Set Cnt Reload		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																ACNTRLD															

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Read returns 0.	R	0x0000
15:0	ACNTRLD	A-Cnt Reload value for Source Active Register set. Value copied from PCNT.ACNT: Represents the originally programmed value of ACNT. The Reload value is used to reinitialize ACNT after each array is serviced (i.e., ACNT decrements to 0). by the Src offset in bytes between the starting address of each source array (recall that there are BCNT arrays of ACNT bytes)	R	0x0000

### 1.5.7.27 TPTCj\_SASRCBREF

**Table 1-240. TPTCj\_SASRCBREF**

<b>Address Offset</b>	0x25C		
<b>Physical address</b>	0x01C1 025C	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 065C	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Src Actv Set Src Addr A-Reference		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SADDRBREF																															

Bits	Field Name	Description	Type	Reset
31:0	SADDRBREF	Source address reference for Source Active Register Set: Represents the starting address for the array currently being read. The next arrays starting address is calculated as the reference address plus the source b-idx value.	R	0x00000000

### 1.5.7.28 TPTCj\_SADSTBREF

**Table 1-241. TPTCj\_SADSTBREF**

<b>Address Offset</b>	0x260		
<b>Physical address</b>	0x01C1 0260	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0660	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	rsvd, return 0x0 w/o AERROR		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DADDRBREF																															

Bits	Field Name	Description	Type	Reset
31:0	DADDRBREF	Dst address reference is not applicable for Src Active Register Set. Reads return 0x0.	R	0x00000000

### 1.5.7.29 TPTCj\_DFCNTRLD

**Table 1-242. TPTCj\_DFCNTRLD**

<b>Address Offset</b>	0x280		
<b>Physical address</b>	0x01C1 0280	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0680	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Dst FIFO Set Cnt Reload		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																ACNTRLD															

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Read returns 0.	R	0x0000
15:0	ACNTRLD	A-Cnt Reload value for Destination FIFO Register set. Value copied from PCNT.ACNT: Represents the originally programmed value of ACNT. The Reload value is used to reinitialize ACNT after each array is serviced (i.e., ACNT decrements to 0). by the Src offset in bytes between the starting address of each source array (recall that there are BCNT arrays of ACNT bytes)	R	0x0000

### 1.5.7.30 TPTCj\_DF\_SRCBREF

### Table 1-243. TPTCj\_DFSRCBREF

[illegible]

### 1.5.7.31 TPTCj\_DFDSTBREF

Table 1-244. TPTCj DFDSTBREF

<b>Address Offset</b>	0x288		
<b>Physical address</b>	0x01C1 0288	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0688	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Dst FIFO Set Dst Addr A-Reference		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DADDRBREF																															

Bits	Field Name	Description	Type	Reset
31:0	DADDRBREF	Destination address reference for Dst FIFO Register Set: Represents the starting address for the array currently being written. The next arrays starting address is calculated as the reference address plus the dest bid xvalue.	R	0x00000000

### 1.5.7.32 TPTCj\_DFOPTi

**Table 1-245. TPTCj\_DFOPTi**

<b>Address Offset</b>	0x300 + (0x40*i)		
<b>Physical address</b>	0x01C1 0300 + (0x40*i)	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 0700 + (0x40*i)	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Dst FIFO i Set Options		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								TCCHEN	Reserved	TCINTEN	Reserved	TCC				Reserved	FWID				Reserved	PRI				Reserved	DAM	SAM			

Bits	Field Name	Description	Type	Reset
31:23	Reserved	Read returns 0.	R	0x000
22	TCCHEN	Transfer complete chaining enable: 0: Transfer complete chaining is disabled. 1: Transfer complete chaining is enabled.	R	0
21	Reserved	Read returns 0.	R	0
20	TCINTEN	Transfer complete interrupt enable: 0: Transfer complete interrupt is disabled. 1: Transfer complete interrupt is enabled.	R	0
19:18	Reserved	Read returns 0.	R	0x0
17:12	TCC	Transfer Complete Code: The 6-bit code is used to set the relevant bit in CER or IPR of the TPCC module.	R	0x00
11	Reserved	Read returns 0.	R	0
10:8	FWID	FIFO width control: Applies if either SAM or DAM is set to FIFO mode.  Read 0x0: FIFO width is 8-bit Read 0x1: FIFO width is 16-bit Read 0x2: FIFO width is 32-bit Read 0x3: FIFO width is 64-bit Read 0x4: FIFO width is 128-bit Read 0x5: FIFO width is 256-bit	R	0x0
7	Reserved	Read returns 0.	R	0
6:4	PRI	Transfer Priority: 0: Priority 0 - Highest priority 1: Priority 1 ... 7: Priority 7 - Lowest priority Read 0x0: Priority 0 - Highest priority Read 0x1: Priority 1 Read 0x2: Priority 2 Read 0x3: Priority 3 Read 0x4: Priority 4 Read 0x5: Priority 5 Read 0x6: Priority 6 Read 0x7: Priority 7 - Lowest Priority	R	0x0
3:2	Reserved	Read returns 0.	R	0x0

Bits	Field Name	Description	Type	Reset
1	DAM	Destination Address Mode within an array: 0: INCR, Dst addressing within an array increments. 1: FIFO, Dst addressing within an array wraps around upon reaching FIFO width.	R	0
0	SAM	Source Address Mode within an array: 0: INCR, Src addressing within an array increments. 1: FIFO, Src addressing within an array wraps around upon reaching FIFO width.	R	0

### 1.5.7.33 TPTCj\_DFSCi

**Table 1-246. TPTCj\_DFSCi**

<b>Address Offset</b>	0x304 + (0x40*i)																																
<b>Physical address</b>	0x01C1 0304 + (0x40*i)																<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 0704 + (0x40*i)																<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	rsvd, return 0x0 w/o AERROR																																
<b>Type</b>	R																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SADDR																															

Bits	Field Name	Description	Type	Reset
31:0	SADDR	Source address is not applicable for Dst FIFO Register Set: Reads return 0x0.	R	0x00000000

### 1.5.7.34 TPTCj\_DFCNTi

**Table 1-247. TPTCj\_DFCNTi**

<b>Address Offset</b>	0x308 + (0x40*i)																																
<b>Physical address</b>	0x01C1 0308 + (0x40*i)																<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 0708 + (0x40*i)																<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	Dst FIFO i Set Count																																
<b>Type</b>	R																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	B-Count Remaining for Dst Register Set: Number of arrays to be transferred, where each array is ACNT in length. Represents the amount of data remaining to be written. Initial value is copied from PCNT. TC decrements ACNT and BCNT as necessary after each write dataphase is issued. Final value should be 0 when TR is complete.	R	0x0000
15:0	ACNT	A-Count Remaining for Dst Register Set: Number of bytes to be transferred in first dimension. Represents the amount of data remaining to be written. Initial value is copied from PCNT. TC decrements ACNT and BCNT as necessary after each write dataphase is issued. Final value should be 0 when TR is complete.	R	0x0000

### 1.5.7.35 TPTCj\_DFDSTi

**Table 1-248. TPTCj\_DFDSTi**

<b>Address Offset</b>	0x30C + (0x40*i)															
<b>Physical address</b>	0x01C1 030C + (0x40*i)															
<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 070C + (0x40*i)															
<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	Dst FIFO i Set Dst Address															
<b>Type</b>	R															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DADDR																															

Bits	Field Name	Description	Type	Reset
31:0	DADDR	Destination address for Dst FIFO Register Set: Initial value is copied from PDST.DADDR. TC updates value according to destination addressing mode (OPT.SAM) and/or dest index value (BIDX.DBIDX) after each write command is issued. When a TR is complete, the final value should be the address of the last write command issued.	R	0x00000000

### 1.5.7.36 TPTCj\_DFBIDXi

**Table 1-249. TPTCj\_DFBIDXi**

<b>Address Offset</b>	0x310 + (0x40*i)															
<b>Physical address</b>	0x01C1 0310 + (0x40*i)															
<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 0710 + (0x40*i)															
<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	Dst FIFO i Set B-Dim Idx															
<b>Type</b>	R															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBIDX																SBIDX															

Bits	Field Name	Description	Type	Reset
31:16	DBIDX	Dest B-Idx for Dest FIFO Register Set. Value copied from PBIDX: B-Idx offset between Destination arrays: Represents the offset in bytes between the starting address of each destination array (recall that there are BCNT arrays of ACNT elements). DBIDX is always used, regardless of whether DAM is Increment or FIFO mode.	R	0x0000
15:0	SBIDX	Dest B-Idx for Dest FIFO Register Set. Value copied from PBIDX: B-Idx offset between Source arrays: Represents the offset in bytes between the starting address of each source array (recall that there are BCNT arrays of ACNT elements). SBIDX is always used, regardless of whether SAM is Increment or FIFO mode.	R	0x0000

### 1.5.7.37 TPTCj\_DFMPPRXYi

**Table 1-250. TPTCj\_DFMPPRXYi**

<b>Address Offset</b>	0x314 + (0x40*i)																																
<b>Physical address</b>	0x01C1 0314 + (0x40*i)																<b>Instance</b>	IVA2.2 TPTC0															
<b>Physical address</b>	0x01C1 0714 + (0x40*i)																<b>Instance</b>	IVA2.2 TPTC1															
<b>Description</b>	Dst FIFO i Mem Protect Proxy																																
<b>Type</b>	R																																

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																						SECURE	PRIV	Reserved				PRIVID			

Bits	Field Name	Description	Type	Reset
31:10	Reserved	Read returns 0.	R	0x000000
9	SECURE	Secure Level: SECURE = 0: Nonsecure access SECURE = 1: Secure access DFMPPRXYi.SECURE is always updated with the value from the configuration bus secure field on any/every write to Program Set BIDX Register (trigger register). The SECURE value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The secure attribute is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection and security checks based on the SECURE level of the external host that sets up the DMA transaction.	R	0
8	PRIV	Privilege Level: PRIV = 0: User level privilege PRIV = 1: Supervisor level privilege DFMPPRXYi.PRIV is always updated with the value from the configuration bus Privilege field on any/every write to Program Set BIDX Register (trigger register). The PRIV value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the PRIV of the external host that sets up the DMA transaction.	R	0
7:4	Reserved	Read returns 0.	R	0x0
3:0	PRIVID	Privilege ID: DFMPPRXYi.PRIVID is always updated with the value from configuration bus Privilege ID field on any/every write to Program Set BIDX Register (trigger register). The PRIVID value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the privid of the external host that sets up the DMA transaction.	R	0x0

## 1.5.8 SYSC Register Descriptions

This section provides information about the IVA2\_SYSC Module. Each register in the Module is described separately below.

### 1.5.8.1 SYSC\_REVISION

**Table 1-251. SYSC\_REVISION**

<b>Address Offset</b>	0x000																															
<b>Physical address</b>	0x01C2 0000								<b>Instance</b>								IVA2.2 SYSC															
<b>Description</b>	This register contains the IP revision code																															
<b>Type</b>	R																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																								REV								
<b>Bits</b>		<b>Field Name</b>						<b>Description</b>														<b>Type</b>				<b>Reset</b>						
31:8		Reserved						Read returns 0.														R				0x000000						
7:0		REV						IP revision 3:0 Minor revision 7:4 Major revision														R										

### 1.5.8.2 SYSC\_SYSCONFIG

**Table 1-252. SYSC\_SYSCONFIG**

<b>Address Offset</b>	0x008															<b>Instance</b>	IVA2.2 SYSC															
<b>Physical address</b>	0x01C2 0008																															
<b>Description</b>	This register allows controlling various parameters of the SYSC module																															
<b>Type</b>	RW																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																															AUTOIDLE	
<b>Bits</b>		<b>Field Name</b>						<b>Description</b>															<b>Type</b>		<b>Reset</b>							
31:1		Reserved						Write 0s for future compatibility. Read returns 0.															RW		0x00000000							
0		AUTOIDLE						Internal auto-clock gating strategy 0: Clock is free running 1: Automatic clock gating strategy is applied															RW		1							

### 1.5.8.3 SYSC\_LICFG0

**Table 1-253. SYSC\_LICFG0**

<b>Address Offset</b>	0x040	<b>Instance</b>	IVA2.2 SYSC
<b>Physical address</b>	0x01C2 0040		
<b>Description</b>	This register controls various parameters of the IVA2.2 local interconnect network		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																GEMBURSTOPTEN	GEMTRUECOMPEN	Reserved						DMA2DOPTEN	DMATRUERCOMPEN	Reserved				Reserved	PAGEXINGEN	Reserved

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
16	GEMBURSTOPTEN	C64x + Megamodule cache-line operation transfers optimization control: 0: C64x + Megamodule cache operation transfers are not optimized 1: C64x + Megamodule cache operation transfers are optimized	RW	0
15	GEMTRUECOMPEN	C64x + Megamodule program-initiated write-back transfer true completion control: 0: C64x + Megamodule program-initiated write-back transfer completion is not accurate 1: C64x + Megamodule program initiated write-back transfer completion is accurate	RW	0
14:10	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00
9	DMA2DOPTEN	2D transfers optimization control: 0: 2D DMA transfers optimization is disabled 1: 2D DMA transfers optimization is enabled	RW	0
8	DMATRUERCOMPEN	DMA write transfer true completion control: 0: DMA write transfer completion is not accurate 1: DMA write transfer completion is accurate	RW	0
7:4	Reserved	Write 0xF for compatibility. Read returns 0xF	RW	0xF
3:2	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0
1	PAGEXINGEN	MMU page crossing enable: 0: Bursts are not allowed to cross 4KB page boundaries 1: Bursts are allowed to cross 4KB page boundaries	RW	0
0	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0

### 1.5.8.4 SYSC\_LICFG1

**Table 1-254. SYSC\_LICFG1**

Address Offset	0x048																Instance	IVA2.2 SYSC																
Physical address	0x01C2 0048																																	
Description	This register allows controlling various parameters of the IVA2.2 local interconnect network																																	
Type	RW																																	
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
Reserved																												APINTERVAL						
Bits	Field Name																Description																Type	Reset
31:5	Reserved																Write 0s for future compatibility. Read returns 0.																RW	0x0000000
4:0	APINTERVAL																Control of the Aged Priority (priority inversion) for DMA accesses:  When set to 0x0, the aged priority is disabled  When set to another value, this controls how often the priority is adjusted: every APInterval cycles, the priority of the port is decreased until the associated request is accepted or the priority of the port equals 0. The priority of the port is reinitialized to the transaction priority each time a new VBUS command is generated, i.e. the last one has been accepted.  0x0: Aged Priority Disabled:  There is no aged priority in SCR. DMA transaction keeps the fixed priority defined internally, and has to wait for the bus to be freed by higher priority initiators  Aged Priority Disabled:																RW	0x00

### 1.5.8.5 SYSC\_BOOTADDR

**Table 1-255. SYSC\_BOOTADDR**

<b>Address Offset</b>	0x100																																																																																														
<b>Physical address</b>	0x01C2 0100																<b>Instance</b> IVA2.2 SYSC																																																																														
<b>Description</b>	This register defines the physical address of the IVA2 boot loader. This is a copy of the CONTROL_IVA2_BOOTADDR when the IVA2 is released from reset.																																																																																														
<b>Type</b>	R																																																																																														
<table><tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr><tr><td colspan="20">BOOTLOADADDR</td><td colspan="12">Reserved</td></tr></table>																																31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	BOOTLOADADDR																				Reserved

<b>Bits</b>	<b>Field Name</b>		<b>Description</b>																			<b>Type</b>		<b>Reset</b>																																																																							
31:12	BOOTLOADADDR		Physical address of the IVA2 boot loader: This is the read-only copy of the CONTROL_IVA2_BOOTADDR when the IVA2 is released from reset This is an index to a 4K-byte page																			R		0x----																																																																							
11:0	Reserved		Read returns 0.																			R		0x000																																																																							

### 1.5.8.6 SYSC\_BOOTMOD

**Table 1-256. SYSC\_BOOTMOD**

<b>Address Offset</b>	0x104																																																																																																					
<b>Physical address</b>	0x01C2 0104								<b>Instance</b> IVA2.2 SYSC																																																																																													
<b>Description</b>	This register defines the IVA2 boot mode. This is a copy of the CONTROL_IVA2_BOOTMOD when the IVA2 is released from reset.																																																																																																					
<b>Type</b>	R																																																																																																					
<table><tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr><tr><td colspan="28">Reserved</td><td colspan="5"></td><td colspan="5">BOOTMODE</td></tr></table>																																	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Reserved																																	BOOTMODE				
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																																																																							
Reserved																																	BOOTMODE																																																																					
<b>Bits</b>	<b>Field Name</b>		<b>Description</b>																			<b>Type</b>		<b>Reset</b>																																																																														
31:4	Reserved		Read returns 0.																			R		0x0000000																																																																														
3:0	BOOTMODE		Boot mode of the IVA2: This is the read-only copy of the IVA2_BOOTMOD when the IVA2 is released from reset The value meaning is defined by the IVA2 ROM boot code																			R		0x-																																																																														

## 1.5.9 WUGEN Register Descriptions

This section provides information about the WUGEN Module. Each register in the Module is described separately below.

### 1.5.9.1 WUGEN\_REVISION

**Table 1-257. WUGEN\_REVISION**

<b>Address Offset</b>	0x000	<b>Instance</b>	IVA2.2 WUGEN
<b>Physical address</b>	0x01C2 1000		
<b>Description</b>	This register contains the IP revision code		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																REV															

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Read returns 0.	R	0x000000
7:0	REV	IP revision 3:0 Minor revision 7:4 Major revision	R	

### 1.5.9.2 WUGEN\_SYSCONFIG

**Table 1-258. WUGEN\_SYSCONFIG**

<b>Address Offset</b>	0x008	<b>Instance</b>	IVA2.2 WUGEN
<b>Physical address</b>	0x01C2 1008		
<b>Description</b>	This register allows controlling various parameters of the WUGEN module		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																															AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:1	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00000000
0	AUTOIDLE	Internal auto-clock gating strategy 0: Clock is free running 1: Automatic clock gating strategy is applied	RW	1

### 1.5.9.3 WUGEN\_MEVT0

**Table 1-259. WUGEN\_MEVT0**

Address Offset		0x060																Instance		IVA2.2 WUGEN									
Physical address		0x01C2 1060																											
Description		This register contains the interrupt mask (LSB)																											
Type		R																											

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 1.5.10 IA\_GEM Register Descriptions

This section provides information about the Initiator Agent for the C64x + Megamodule Module. Each register in the module is described separately below.

#### 1.5.10.1 GEM\_AGENT\_STATUS

**Table 1-274. GEM\_AGENT\_STATUS**

Address Offset		0x0000 0028																Instance		IA_GEM																	
Physical Address		0x000F 8828																																			
Description		Agent Status Register																																			
Type		R																																			
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
RESERVED		INBAND_ERROR_SECONDARY		INBAND_ERROR_PRIMARY		RESERVED		MERROR		RESERVED						BURST_TIMEOUT		TIMEBASE				RESERVED		RESP_TIMEOUT		READEX		BURST		RESP_WAITING		REQ_ACTIVE		RESERVED		CORE_RESET	

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Reserved	R	0x0
29	INBAND_ERROR_SECONDARY	Error Status for in-band errors with MErrSteer indicating a secondary error. Read 0x0: No in-band error received Write 0x0: Ignored Read 0x1: In-band error received Write 0x1: Clear in-band error	R/W	0x0
28	INBAND_ERROR_PRIMARY	Error Status for in-band errors with MErrSteer indicating Primary Error Read 0x0: No in-band error received Write 0x0: Ignored Read 0x1: In-band error received Write 0x1: Clear in-band error	R/W	0x0
27:25	RESERVED	Reserved	R	0x0
24	MERROR	MError assertion detected	R	0x0
23:17	RESERVED	Reserved	R	0x00
16	BURST_TIMEOUT	Status of open burst and	R	0x0
15:12	TIMEBASE	Observation of timebase signals for internal verification	R	0x0
11:9	RESERVED	Reserved	R	0x0
8	RESP_TIMEOUT	Response timeout status	R	0x0
7	READEX	Status of ReadEx/Write	R	0x0
6	BURST	Status of open burst	R	0x0
5	RESP_WAITING	Responses waiting	R	0x0
4	REQ_ACTIVE	Requests outstanding	R	0x0
3:1	RESERVED	Reserved	R	0x0
0	CORE_RESET	Reset input from core interface	R	0x0

### 1.5.11 IA\_EDMA Register Descriptions

This section provides information about the Initiator Agent for the EDMA module. Each register in the module is described separately below.

#### 1.5.11.1 EDMA\_AGENT\_STATUS

**Table 1-275. EDMA\_AGENT\_STATUS**

Address Offset		0x0000 0028																Instance																IA_EDMA																																									
Physical Address		0x000F 8C28																																																																									
Description		Agent Status Register																																																																									
Type		R																																																																									
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																																												
RESERVED				INBAND_ERROR_SECONDARY				INBAND_ERROR_PRIMARY				RESERVED				MERROR				RESERVED								BURST_TIMEOUT				TIMEBASE								RESERVED				RESP_TIMEOUT				READEX				BURST				RESP_WAITING				REQ_ACTIVE				RESERVED								CORE RESET			

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Reserved	R	0x0
29	INBAND_ERROR_SECONDARY	Error Status for in-band errors with MErrSteer indicating a secondary error. Read 0x0: No in-band error received Write 0x0: Ignored Read 0x1: In-band error received Write 0x1: Clear in-band error	R/W	0x0
28	INBAND_ERROR_PRIMARY	Error Status for in-band errors with MErrSteer indicating Primary Error Read 0x0: No in-band error received Write 0x0: Ignored Read 0x1: In-band error received Write 0x1: Clear in-band error	R/W	0x0
27:25	RESERVED	Reserved	R	0x0
24	MERROR	MError assertion detected	R	0x0
23:17	RESERVED	Reserved	R	0x00
16	BURST_TIMEOUT	Status of open burst and	R	0x0
15:12	TIMEBASE	Observation of timebase signals for internal verification	R	0x0
11:9	RESERVED	Reserved	R	0x0
8	RESP_TIMEOUT	Response timeout status	R	0x0
7	READEX	Status of ReadEx/Write	R	0x0
6	BURST	Status of open burst	R	0x0
5	RESP_WAITING	Responses waiting	R	0x0
4	REQ_ACTIVE	Requests outstanding	R	0x0
3:1	RESERVED	Reserved	R	0x0

<b>Bits</b>	<b>Field Name</b>	<b>Description</b>	<b>Type</b>	<b>Reset</b>
0	CORE_RESET	Reset input from core interface	R	0x0

## 1.6 Revision History

[Table 1-276](#) lists the changes made since the previous version of this document.

## 1.1 Display Interface Subsystem Overview

---

**Note:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *OMAP35x Family* section, and your device-specific data manual.

---

The display interface subsystem provides the logic to display a video frame from the memory frame buffer (either SDRAM or SRAM) on a liquid-crystal display (LCD) panel or a TV set. The display subsystem integrates the following elements:

- Display controller (DISPC) module
- Remote frame buffer interface (RFBI) module
- Serial display interface (SDI) complex input/output (I/O) module with the associated phased-locked loop (PLL)
- Display serial interface (DSI) complex I/O module and a DSI protocol engine
- DSI PLL controller that drives a DSI PLL and high-speed (HS) divider
- NTSC/PAL video encoder

The display controller and the DSI protocol engine are connected to the L3 and L4 interconnect; the RFBI and the TV out encoder modules are connected to the L4 interconnect.

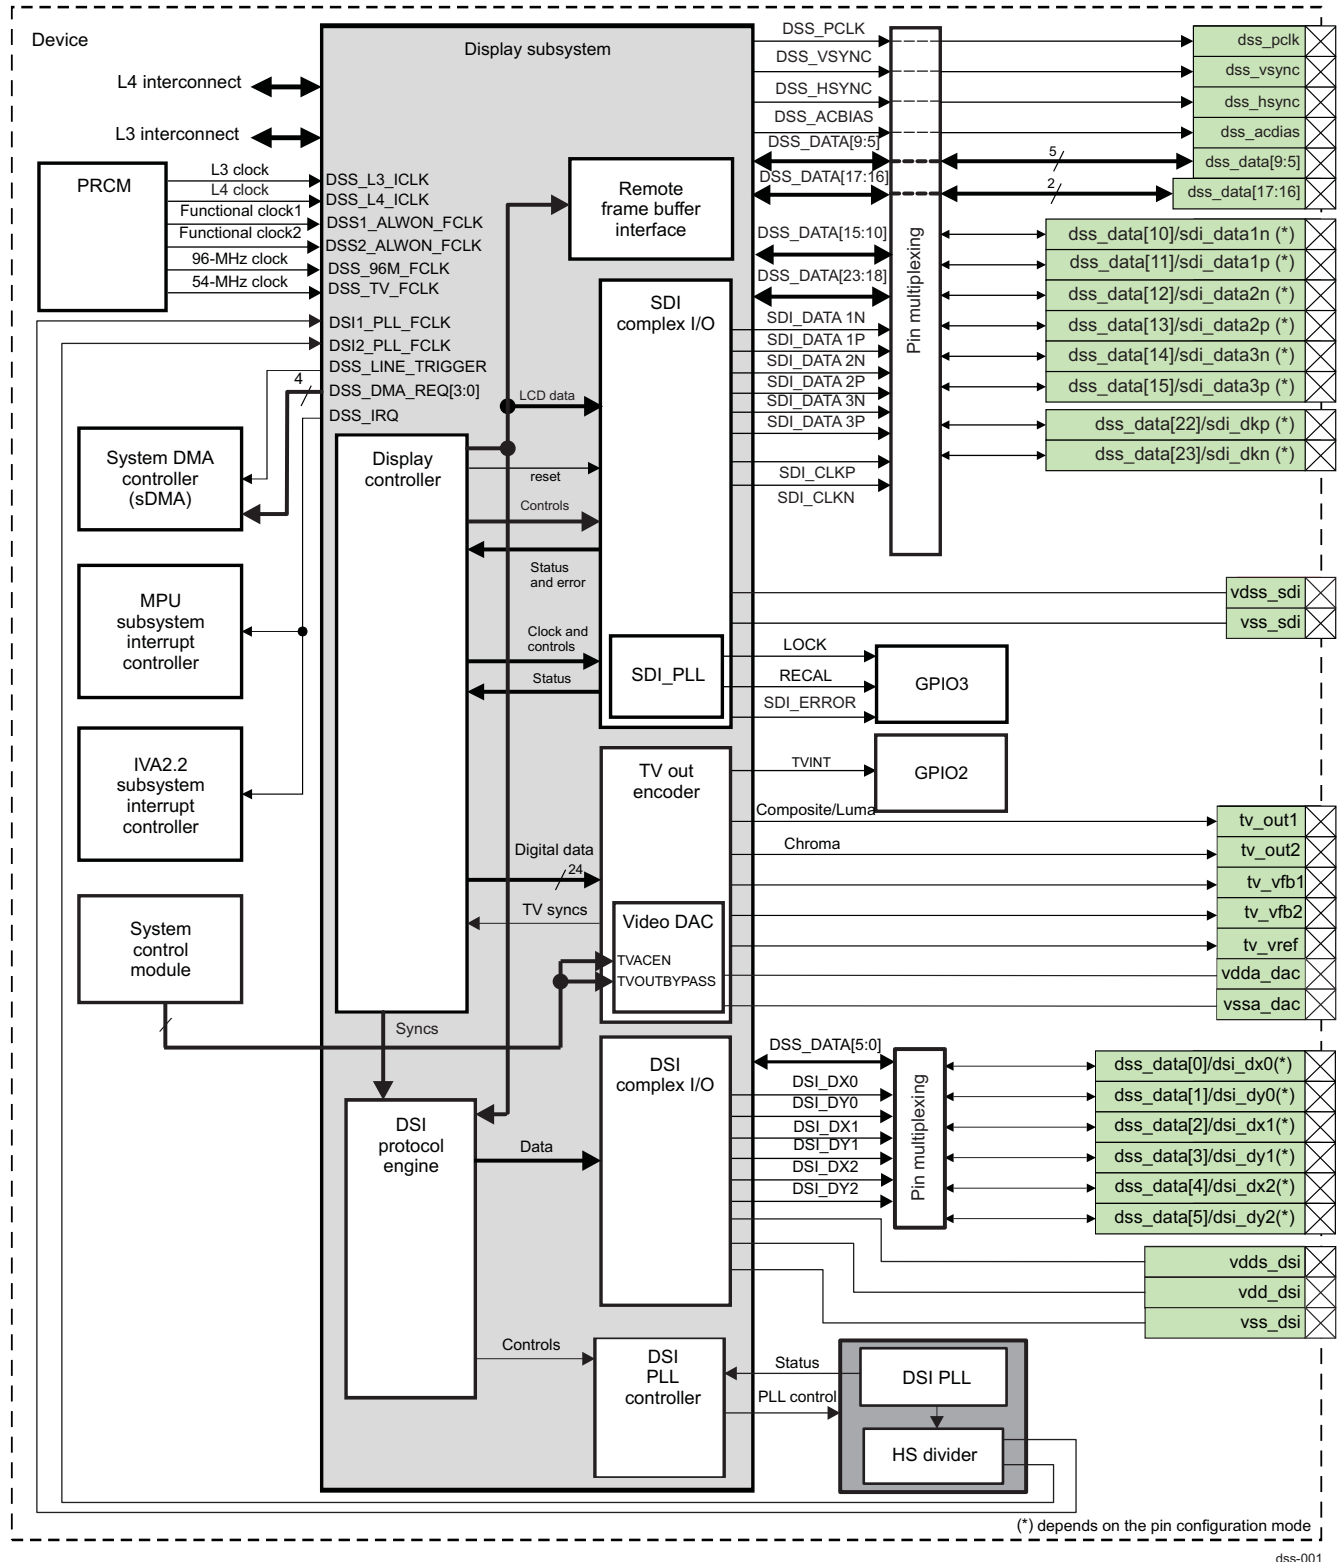

---

**Note:** The SDI module, the DSI complex I/O module, and the DSI PLL controller are not connected to an L3 or L4 interconnect. Specific display subsystem registers manage their programmable features.

---

Figure 1-1 shows a block diagram of the display subsystem.

Figure 1-1. Display Subsystem Highlight

**Note:** For more information about connecting the LOCK, RECAL, SDI\_ERROR, and TVINT signals through the GPIO2 and GPIO3 modules, see the *GPIO* chapter.

The display subsystem includes the following main features:

- Display controller
    - Display modes
      - Programmable pixel display modes (1, 2, 4, 8, 12, 16, and 24 bits-per-pixel [BPP] modes)
      - Programmable display size supported:
        - XGA - 1024x768 VESA Timings at 60 fps (pixel clock = 63.5 MHz )
        - WXGA - 1280x800 VESA timings at 59.91 fps (pixel clock = 71MHz)
        - SXGA+ - 1400x1050 Direct drive of LCD with minimal blanking at 50 fps (pixel clock = 75MHz)
        - HD 720p - 1280x720 CEA 861-D TIMINGS at 60 fps (pixel clock = 74.25 MHz)
      - 256 x 24-bit entries palette in red, green, and blue (RGB)
      - Programmable pixel rate up to 75 MHz
- 
- Note:** The panel size is programmable and can be any width that is a multiple of 8 pixels (line length) in the range [1:2048] pixels (in the case of the RFBI mode, the minimum transfer size is a byte). The maximum resolution is 2048 (lines) x 2048 (pixels).
- 
- Display support
    - Four types of displays are supported: Passive (super-twist nematic [STN]) and active (thin-film transistor [TFT]) colors, passive (STN), and active (TFT) monochromes.
    - 4-/8-bit monochrome passive matrix panel interface support (15 grayscale levels supported using dithering block)
    - 8-bit color passive matrix panel interface support (3375 colors supported for a color panel using dithering block)
    - 12-/16-/18-/24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
    - Remote frame buffer support through the RFBI module
    - Partial display through the RFBI module
    - Second 24-bit digital output
    - Multiple-cycle output format on 8-/9-/12-/16-bit interface time division multiplexing (TDM)
  - Signal processing
    - Overlay support for graphics (ARGB, RGBA, RGB or Color Look Up Table (CLUT)) and video1 (YCbCr 4:2:2, or ARGB, RGBA, RGB), video2 (YCbCr 4:2:2, or ARGB, RGBA, RGB)
    - Programmable video resizer independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4), maximum input width of 1024 pixels in 5-tap mode, and 2048 pixels in 3-tap configurations; no limitation on the input height
    - Rotation 90-, 180-, and 270-degrees
    - Transparency color key (source and destination)
    - Synchronized buffer update
    - Programmable video color space conversion YCbCr 4:2:2 into RGB
    - Hardware cursor
    - Gamma curve support on LCD output
    - Multiple-buffer support
    - Mirroring support
    - Programmable color phase rotation (CPR)
    - Alpha blending support (no rescaling in ARGB or RGBA formats)
  - Advanced
    - Self-refresh using the DMA FIFO
    - Arbitration between high/low priority (graphics video1 and video2)
    - FIFO handcheck in STALL mode
  - Power modes: Low-power saving modes
  - RFBI (MIPI® DBI protocol)

- Access to remote frame buffer (RFB) direct microprocessor unit (MPU) interface
  - Sends commands to the RFB panel through the L4 interconnect
  - Sends data to the RFB panel, received from the display controller or from the MPU through the DISPC pixel data bus
  - Reads data/status from the RFB to the L4 interconnect
- RFB interface
  - 8-/9-/12-/16-bit 8086-series parallel interface
  - Two programmable configurations for two devices connected to the RFBI module
- Data formats
  - Programmable pixel modes (12-/16-/18-/24-BPP modes in RGB format)
  - Programmable output formats on one/multiple cycles per pixel (data from the display controller and from the L4 interconnect)
- Interconnect/FIFO
  - One slave port with DMA request and Interconnect FIFO of 24x32-bit depth (for write access to DSS.RFBI\_DATA register only)
  - One Video Port FIFO of 8x24-bit depth receiving data from the Display Controller.
- SDI
  - TI Flatlink™3G display interface support
  - Pin multiplexing allows simultaneous operation with a single 9-bit RFBI-driven display (no support for simultaneous dual RFBI panel and SDI.)

The SDI module is not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this module.

---

**Note:** The SDI pins are multiplexed with LCD parallel outputs.

---

- MIPI DSI
  - Transfer pixels and data received on the video port or L4 interconnect to the display through the DSI\_PHY
  - The maximum resolution supported on the video port is XGA at 60 fps with 24-bit pixels (maximum pixel clock of 67 MHz) for low voltage
  - Supports video mode and command mode
  - Bidirectional data link support (only one data lane is used in reverse direction in command mode)
  - Supports up to two data configurable lanes, in addition to the clock signaling (minimum of one data link and maximum of two, depending on speed, signal integrity requirements, and number of displays)
  - Maximum data rate of 800 Mbps per data pair
  - Data splitter for 2-data lane configuration
  - ECC and check-sum generation
  - Burst support for the video mode
  - RGB16, RGB18 (packed and non-packed), and RGB24 formats supported for video mode
  - Serial configuration port (SCP) for the DSI\_PHY complex I/O and DSI PLL
  - Connection to the DSI\_PHY complex I/O through PPI
  - Data interleaving support for one synchronous stream (video mode) from the display controller and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
  - Data interleaving supports up to four interleaved asynchronous streams (command mode) from the interconnect or video port when there is no video mode
  - MIPI DCS support (transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral)
  - Supports selection between low-power state and HS mode between HS packet transfers
  - Generic data type support.

**Note:** The DSI pins are multiplexed with LCD parallel outputs. The DSI module is not available on all devices. See Chapter 1, *OMAP35x Family* section, to check availability of this module.

- Video encoder
  - NTSC/PAL encoder outputs with the following standards:
    - NTSC-J, M
    - PAL-B, D, G, H, I
    - PAL-M
    - CGMS-A as described in the CEA-608-x Standard.
  - Input data interface compatible with the following protocols:
    - 24-bit input bus compatible with external sync
    - RGB 4:4:4
  - Dual output data 10-bit interface for internal digital-to-analog converter (DAC) that supports:
    - Composite video (CVBS)
    - Separate video (S-video)
  - TV output data supports ITU-R BT 470-7 recommendation standard for consumer market
  - Master clock input 13.5 MHz, 27 MHz (supports ITU-R 601 sampling for NTSC/PAL), and 54 MHz
  - Programmable horizontal sync, vertical timing, and waveforms
  - Programmable subcarrier frequency and SCH
  - Internal color bar test pattern generation
  - 2x/4x oversampling
  - Supports square pixel sampling (NTSC: 12.27 MHz, 24.54 MHz, 49.09 MHz PAL: 14.75 MHz, 29.5 MHz, 59 MHz)

#### CAUTION

In square pixel mode, an external clock generator is required to provide sampling frequencies.

- TV detection gating pulse generation

## 1.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

### 1.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

#### 1.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI protocol

The DSS.DISPC\_CONTROL[16:15] GPOUT[1:0] bits control selection of the display subsystem modules (see [Table 1-1](#)).

**Table 1-1. I/O Pad Mode Selection**

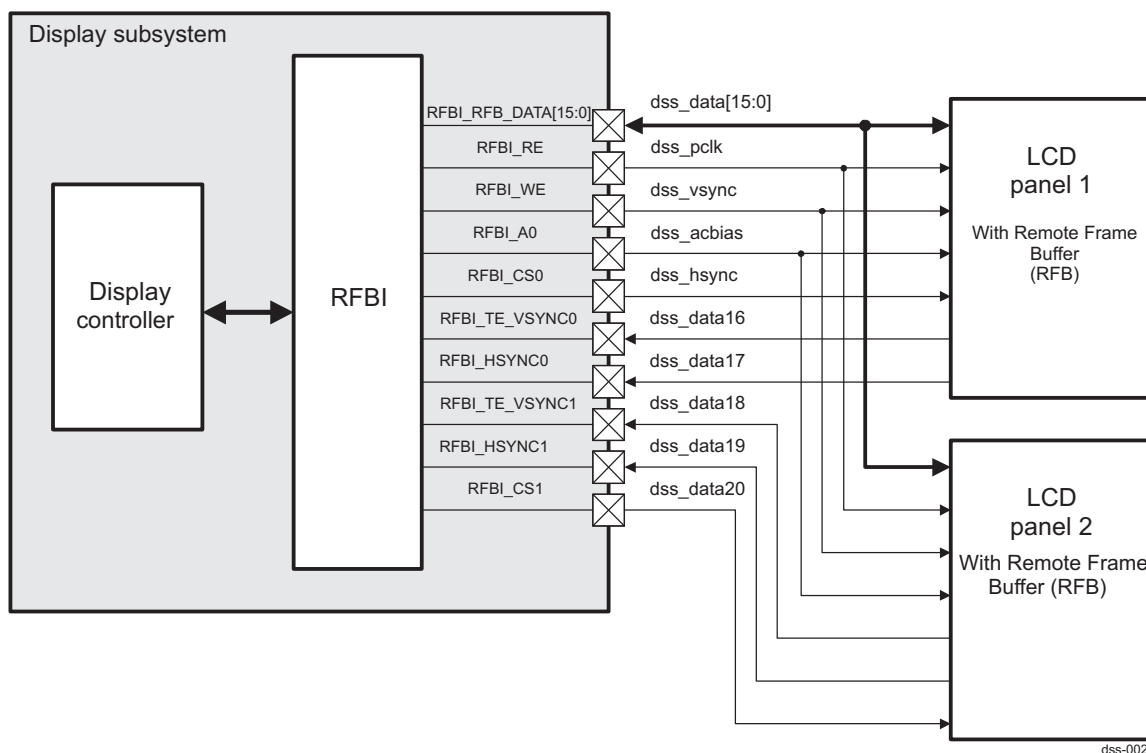

GPOUT1	GPOUT0	Mode Selection
0	0	Reset
0	1	RFBI mode
1	0	Invalid
1	1	Bypass mode

The remote frame buffer (RFB) of the LCD panel is directly connected to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from internal memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

### 1.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

Figure 1-2 shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

**Figure 1-2. LCD Support Parallel Interface (RFBI Mode)**

**Note:** If the SDI is used, the second display device connected to RFB#1 is limited to 9-bit data.

Configure the DSS.RFBI\_CONTROL[3:2] CONFIGSELECT field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 1-2 describes the interface signals to/from the LCD panel in RFBI mode.

**Table 1-2. LCD Interface Signals (RFBI Mode)**

Signal Name	Type <sup>(1)</sup>	Description
RFBI_RFB_DATA[15:0]	I/O	RFBI I/O data
RFBI_RE	O	Read access signal
RFBI_WE	O	Write access signal
RFBI_A0	O	Command/data selection signal
RFBI_CS0	O	Chip-select (CS) signal for LCD 1
RFBI_CS1	O	CS signal for LCD 2
RFBI_TE_VSYNC0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
RFBI_HSYNC0	I	HSYNC from LCD panel 1
RFBI_TE_VSYNC1	I	TE synchronization signal (TE or VSYNC for LCD panel 2)
RFBI_HSYNC1	I	HSYNC from LCD panel 2

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

- **RFBI\_RFB\_DATA[15:0]:** The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.  
Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel module. RFBI\_RFB\_DATA is multiplexed at the chip-level boundary with dss\_data [15:0].
- **RFBI\_RE:** This is the read-enable signal used to indicate when a read from the embedded memory in the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss\_pclk. The read is used to get status/data information from the LCD panel.
- **RFBI\_WE:** The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss\_vsync.
- **RFBI\_A0:** The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI\_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with dss\_acbias.
- **RFBI\_CSx:** The signal is the chip-select (CSx) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CSx must not be changed ( $x = 0$  for LCD panel 1;  $x = 1$  for LCD panel 2). CS0 is multiplexed at the chip-level boundary with dss\_hsync, and CS1 is multiplexed at the chip-level boundary with dss\_data[20].
- **RFBI\_TE\_VSYNCx:** Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI\_TE\_VSYNCx is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.  
To select the trigger mode, configure the DSS.RFBI\_CONFIGi[3:2] TRIGGERMODE field (0x0: Internal trigger mode with the DSS.RFBI\_CONTROL[4] ITE bit, 0x1: External trigger mode with the TE signal RFBI\_TE\_VSYNCx, 0x2: External trigger mode with the RFBI\_TE\_VSYNCx, and RFBI\_HSYNCx signals with the programmable line counter).  
These signals are multiplexed at the chip-level boundary with dss\_data[16] (RFBI\_TE\_VSYNC0) and dss\_data[18] (RFBI\_TE\_VSYNC1) (LCD panel 1:  $x = 0$ ; LCD panel 2:  $x = 1$ ).
- **RFBI\_HSYNCx:** The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI\_HSYNC is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with dss\_data[17] (RFBI\_HSYNC0) and dss\_data[19] (RFBI\_HSYNC1) (LCD panel 1:  $x = 0$ ; LCD panel 2:  $x = 1$ ).

#### 1.2.1.1.1.1 Description of the Tearing Effect Pulse Signal

The externally generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see [Figure 1-3](#)). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

**Figure 1-3. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)**

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.RFBI\_VSYNC\_WIDTH register.

HSYNC is detected based on the minimum pulse width defined by the DSS.RFBI\_HSYNC\_WIDTH register.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI\_TE signal or use a bit field in the RFBI registers to start data capture.

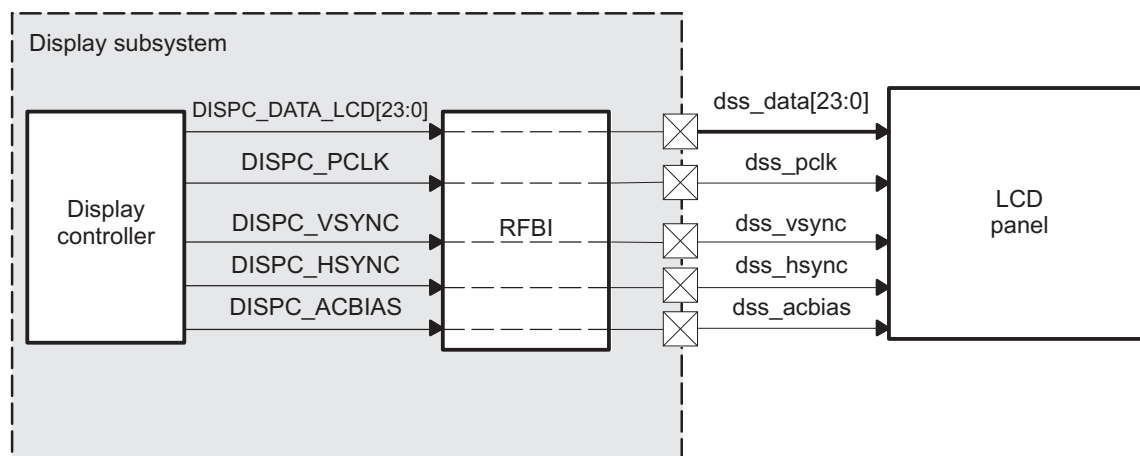

The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. When the line counter reaches the programmable line number, the transfer to the LCD panel begins.

#### 1.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

Figure 1-4 shows the LCD support parallel interface in bypass mode.

**Figure 1-4. LCD Support Parallel Interface (Bypass Mode)**

dss-004

**Note:** In bypass mode, the SDI and the parallel interface cannot be used at the same time.

Table 1-3 describes the interface signals to/from the LCD panel in bypass mode.

**Table 1-3. LCD Interface Signals (Bypass Mode)**

Signal Name	Type <sup>(1)</sup>	Description
DISPC_DATA_LCD[23:0]	O	LCD data from the display controller module
DISPC_PCLK	O	Pixel CLK from the display controller module
DISPC_VSYNC	O	VSYNC from the display controller module
DISPC_HSYNC	O	HSYNC from the display controller module
DISPC_ACBIAS	O	ACBIAS from the display controller module

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

- DISPC\_DATA\_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC\_DATA\_LCD is connected at the chip-level boundary with dss\_data[23:0].
- DISPC\_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss\_pclk.
- DISPC\_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame

clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed on the chip-level boundary with dss\_vsync.

- DISPC\_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal is multiplexed on the chip-level boundary with dss\_hsync.
- DISPC\_ACBIAS: Uses the ac-bias signal from the display controller.
  - In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
  - In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with dss\_acbias.

#### 1.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

Figure 1-5 through Figure 1-11 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

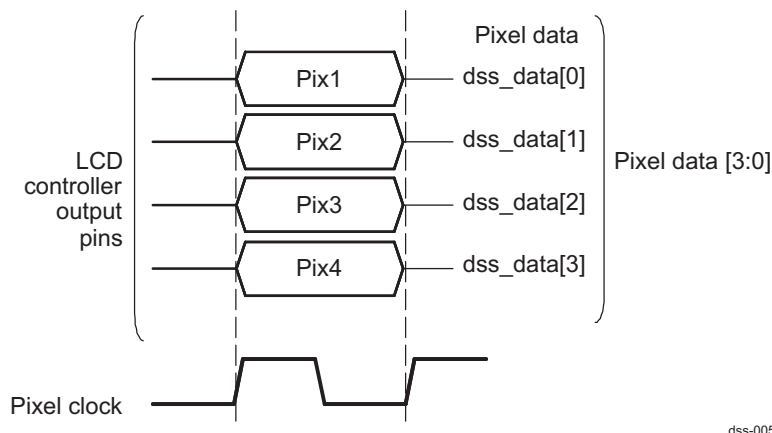

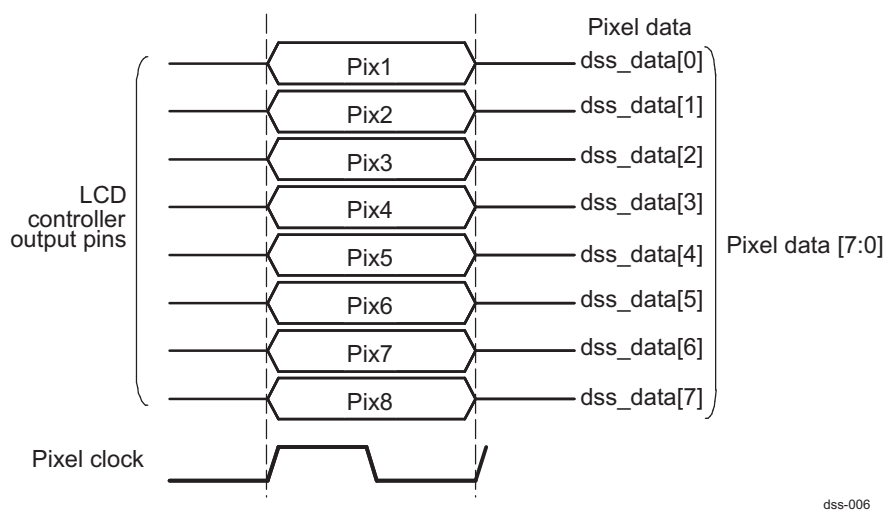

Table 1-4 indicates the number of displayed pixels per pixel clock cycle based on the type of display panel.

**Table 1-4. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type**

Display Panel	Number of Displayed Pixels per Pixel Clock Cycle
Monochrome 4-bit	4
Monochrome 8-bit	8
Passive matrix color	8/3
Active matrix	1

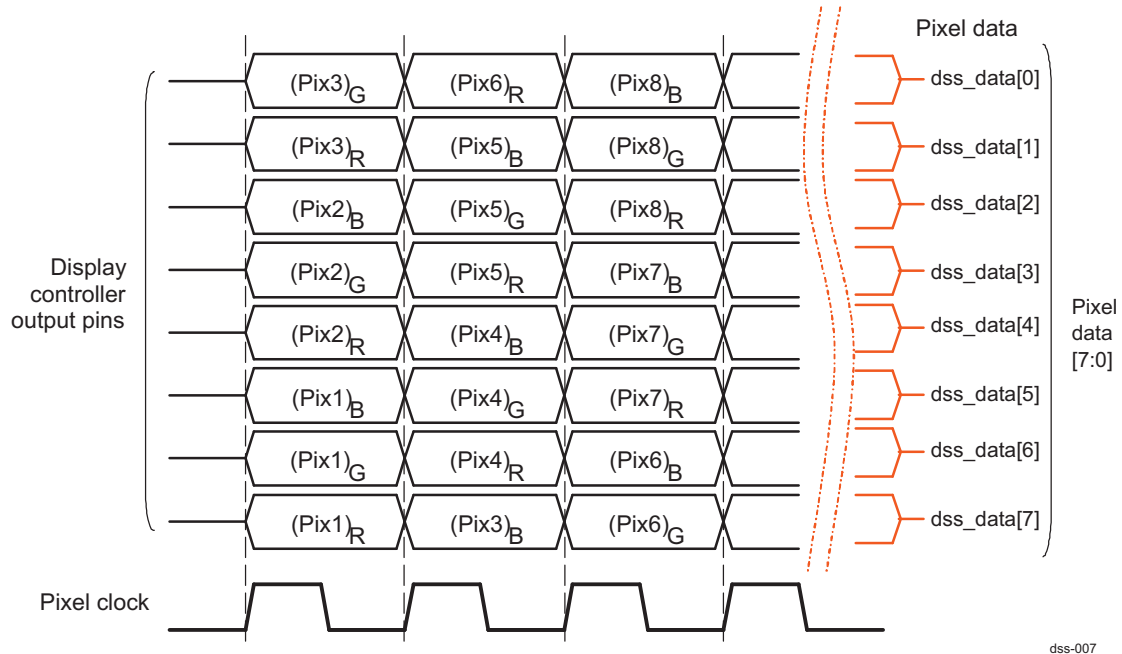

- Passive matrix technology, Monochrome mode  
Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.

Figure 1-5 and Figure 1-6 show 4- and 8-bit monochrome displays, respectively.

**Figure 1-5. LCD Pixel Data Monochrome4 Passive Matrix**

**Figure 1-6. LCD Pixel Data Monochrome8 Passive Matrix**

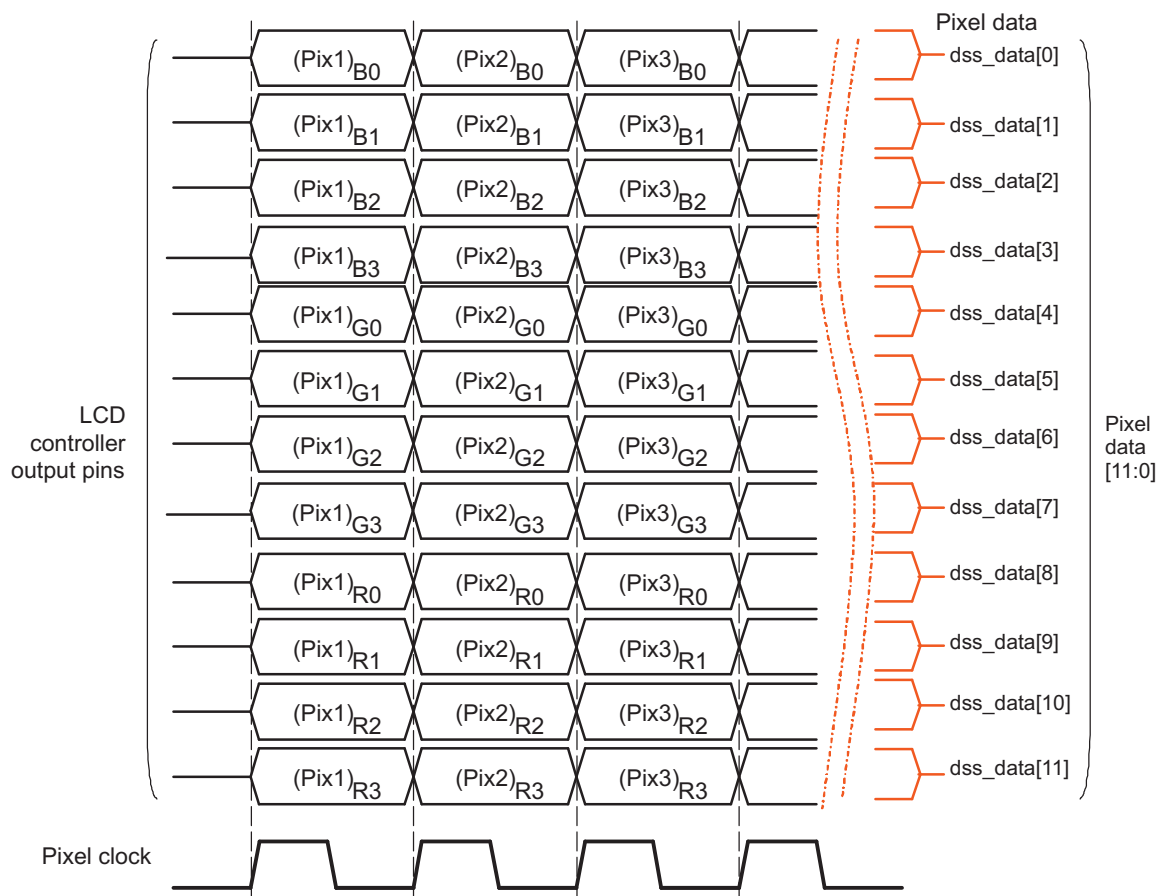

- **Passive matrix technology, Color mode**  
Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).  
[Figure 1-7](#) shows an 8-bit color passive matrix display.

**Figure 1-7. LCD Pixel Data Color Passive Matrix**

- Active matrix technology  
Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.  
[Figure 1-8](#) through [Figure 1-11](#) show 12-, 16-, 18-, and 24-active matrix displays, respectively.

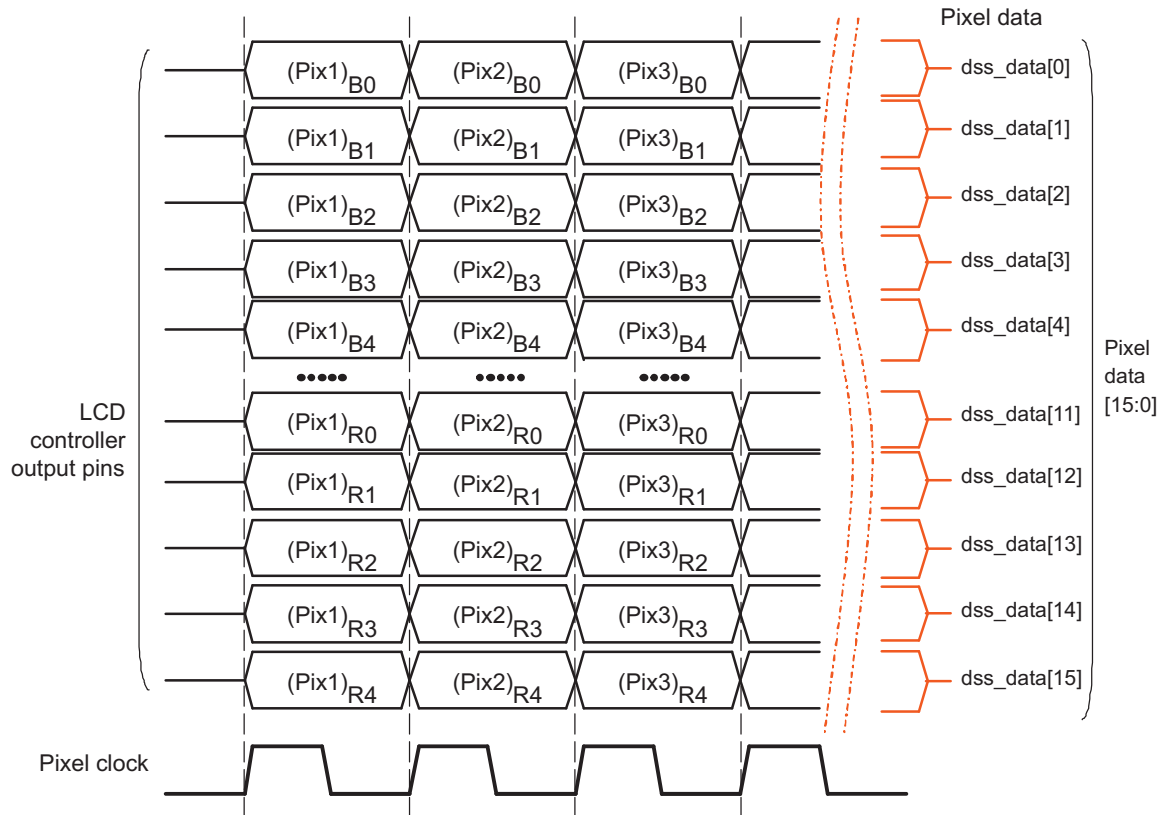

**Figure 1-8. LCD Pixel Data Color12 Active Matrix**

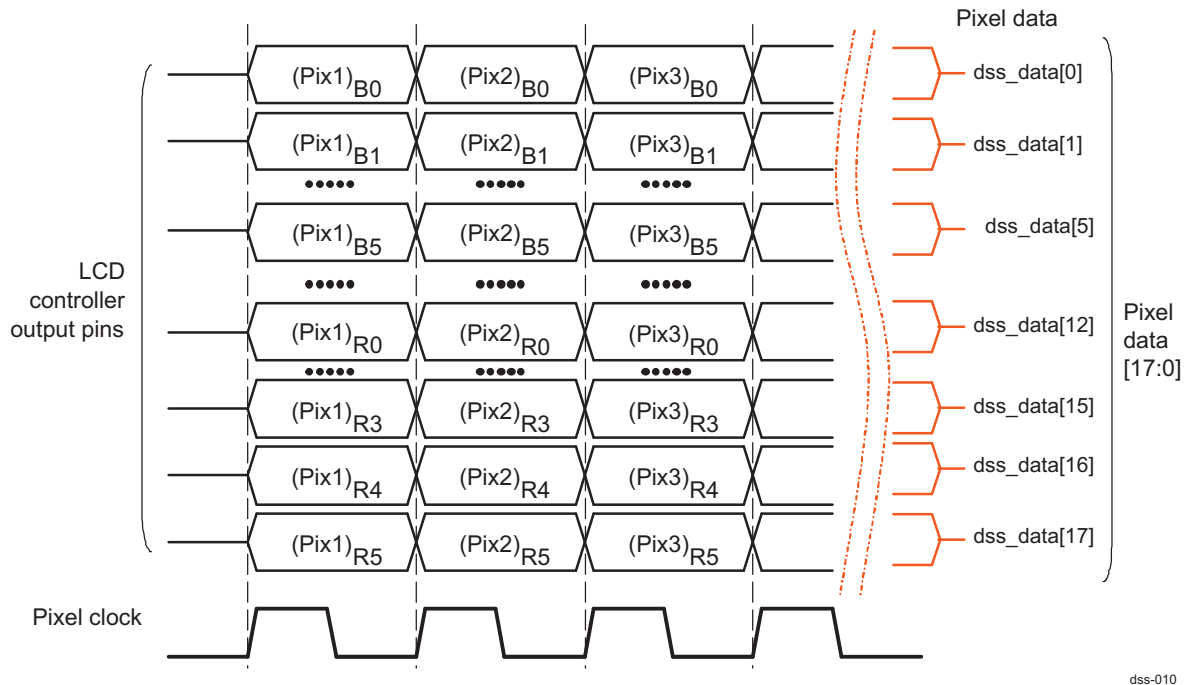

dss-008

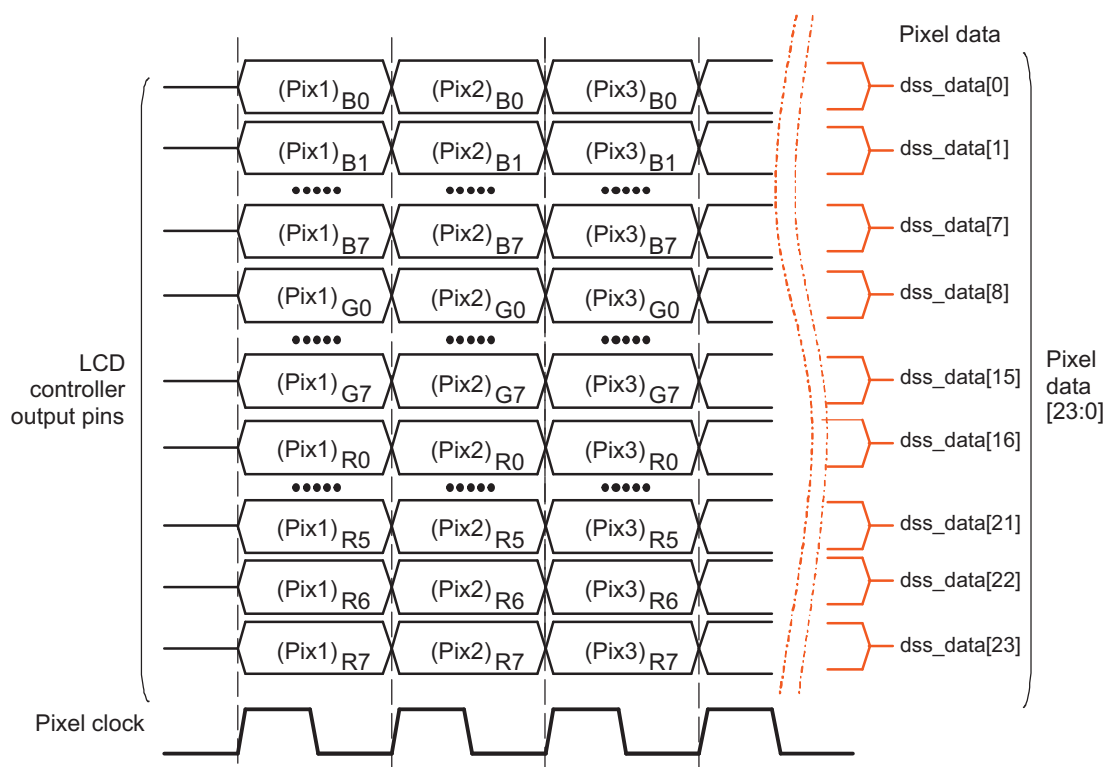

**Figure 1-9. LCD Pixel Data Color16 Active Matrix**

**Figure 1-10. LCD Pixel Data Color18 Active Matrix**

**Figure 1-11. LCD Pixel Data Color24 Active Matrix**

dss-011

- Timing diagrams in flow control mode

- Stall Signal

The stall signal is used in RFBI and DSI modes. In the case of RFBI mode, it is used to indicate when the display controller should stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data should be outputted by the display controller.

**Figure 1-12. RFBI Data Stall Signal Diagram**

dss-134

To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the DSS.DISPC\_CONFIG[16] FIFOHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature should be enabled only when the STALL mode is used (DSS.DISPC\_CONTROL[11] STALLMODE bit set to 1).

When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no DISPC\_PCLK pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow can not occur for the pipelines associated with the LCD output in RFBI mode. [Figure 1-13](#) details the RFBI data stall with FIFO handcheck mode activated.

**Figure 1-13. RFBI Data Stall Signal Diagram With Handcheck**

dss-135

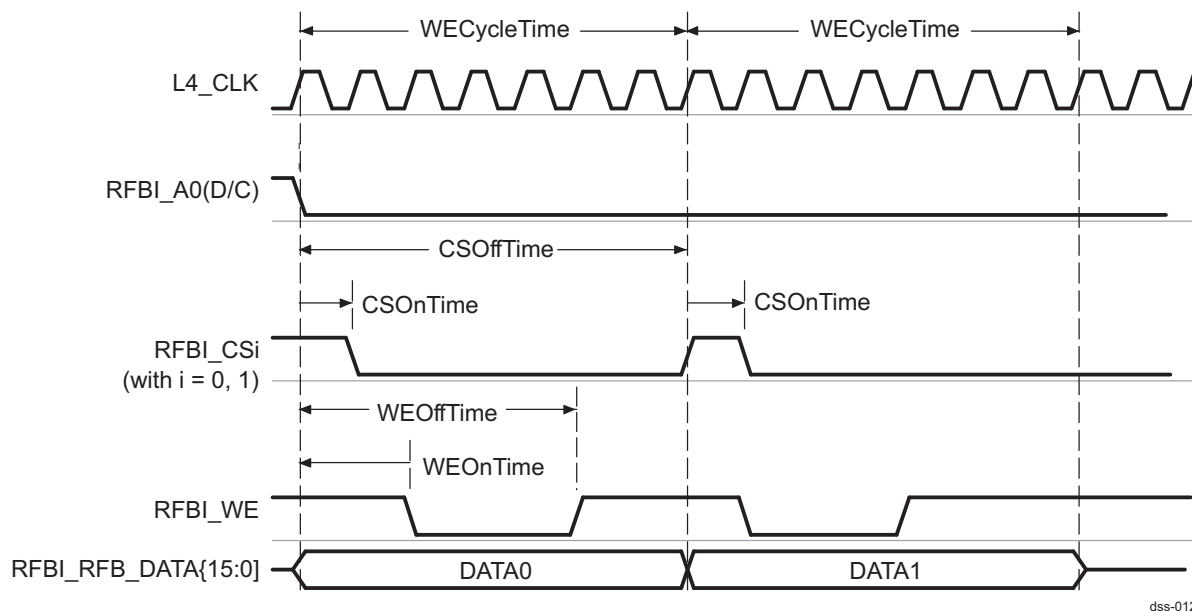

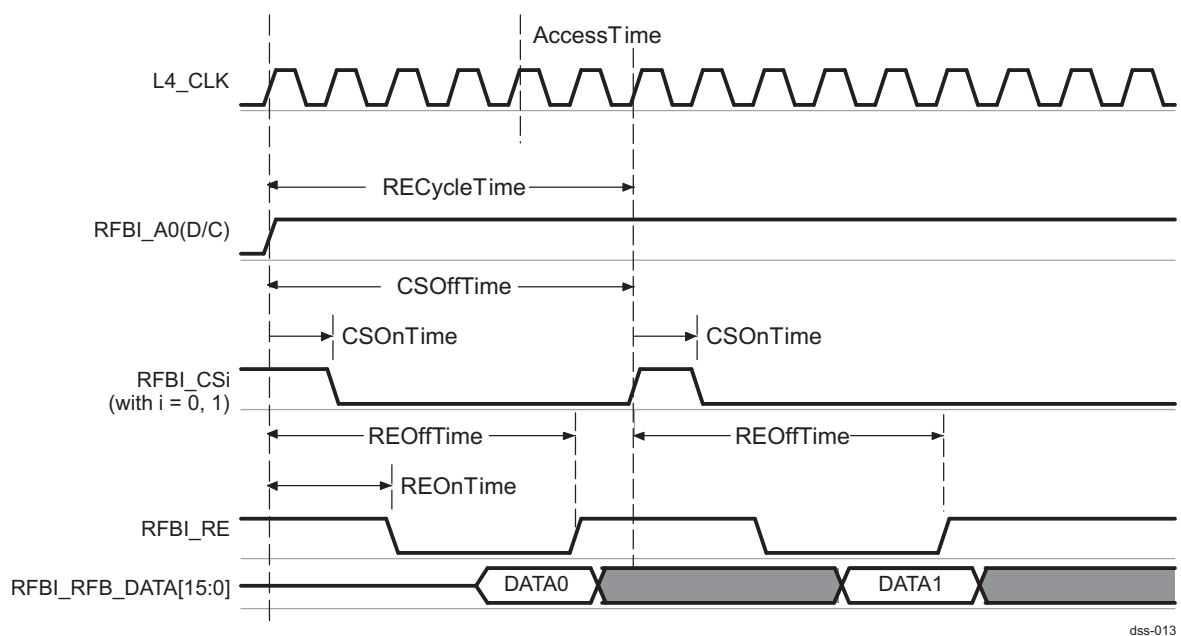

– RFBI timing diagrams

Table 1-5 lists the programmable timing fields. Figure 1-14 through Figure 1-16 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

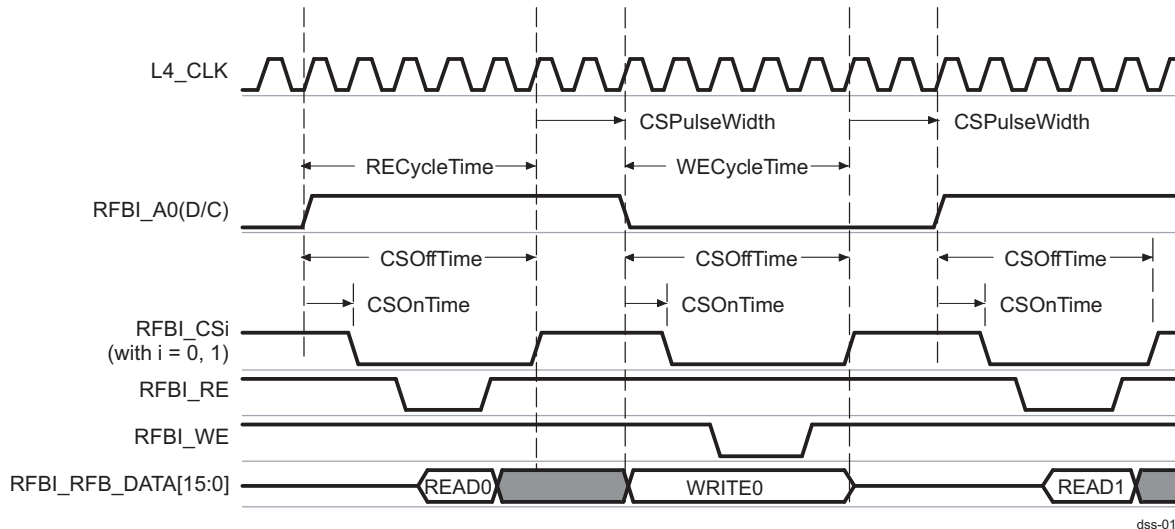

#### 1.2.1.1.4 Transaction Timing Diagrams

**Table 1-5. Programmable Timing Fields in RFBI Mode**

Timing Name	Register Field	Description
CSOnTime	DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME (with i = 0 or 1)	CS assertion time from start access time
CSOffTime	DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME (with i = 0 or 1)	CS deassertion time from start access time
WeCycleTime	DSS.RFBI_CYCLE_TIMEi[5:0] WECYCLETIME (with i = 0 or 1)	The time when A0 becomes valid until write cycle completion
WEOnTime	DSS_RFBI_ONOFF_TIMEi[13:10] WEONTIME (with i = 0 or 1)	WE assertion delay time from start access time
WEOffTime	DSS_RFBI_ONOFF_TIMEi[19:14] WEOFFTIME (with i = 0 or 1)	WE deassertion delay time from start access time
RECycleTime	DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLETIME (with i = 0 or 1)	The time when A0 becomes valid until read cycle completion
REOnTime	DSS_RFBI_ONOFF_TIMEi[23:20] REONTIME (with i = 0 or 1)	RE assertion delay time from start access time
REOffTime	DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME (with i = 0 or 1)	RE assertion delay time from start access time
CSPulseWidth	DSS.RFBI_CYCLE_TIMEi[17:12] CSPULSEWIDTH (with i = 0 or 1)	The time when write cycle time or read cycle time completes

**Figure 1-14. Command Data Write**

**Figure 1-15. Display Data Read**

**Figure 1-16. Read to Write and Write to Read**

- Timing diagrams in bypass mode

Figure 1-17 through Figure 1-32 show timing diagrams of synchronization signals and pixel clock in bypass mode for both passive matrix and active matrix panels. The display controller directly drives these signals, which are related to the programmable fields described in Table 1-6.

**Table 1-6. Programmable Fields in Bypass Mode**

Name	Register	Description
PPL	DSS.DISPC_SIZE_LCD[10:0] PPL field value + 1	Pixels per line
LPP	DSS.DISPC_SIZE_LCD[26:16] LPP field value + 1	Lines per panel
HBP	DSS.DISPC_TIMING_H[31:20] HBP field value + 1	Horizontal back porch
HFP	DSS.DISPC_TIMING_H[19:8] HFP field value + 1	Horizontal front porch
HSW	DSS.DISPC_TIMING_H[7:0] HSW field value + 1	Horizontal synchronization pulse width
VBP	DSS.DISPC_TIMING_V[31:20] VBP field value	Vertical back porch
VFP	DSS.DISPC_TIMING_V[19:8] VFP field value	Vertical front porch
VSW	DSS.DISPC_TIMING_V[7:0] VSW field value + 1	Vertical synchronization pulse width
ONOFF	DSS.DISPC_POL_FREQ[17] ONOFF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock control
RF	DSS.DISPC_POL_FREQ[16] RF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock edge control
IEO	DSS.DISPC_POL_FREQ[15] IEO bit	Invert DISPC_ACBIAS
IPC	DSS.DISPC_POL_FREQ[14] IPC bit	Invert DISPC_PCLK
IHS	DSS.DISPC_POL_FREQ[13] IHS bit	Invert DISPC_HSYNC
IVS	DSS.DISPC_POL_FREQ[12] IVS bit	Invert DISPC_VSYNC

- Active matrix timing configuration 1

- DSS.DISPC\_POL\_FREQ[17] ONOFF bit = 0
- DSS.DISPC\_POL\_FREQ[16] RF bit = 0  
The DISPC\_HSYNC and DISPC\_VSYNC signals are driven on the opposite edge of DISPC\_PCLK from the pixel data.
- DSS.DISPC\_POL\_FREQ[15] IEO = 0  
The DISPC\_ACBIAS signal is active high.
- DSS.DISPC\_POL\_FREQ[14] IPC = 0  
The pixel data are driven on the rising edge of DISPC\_PCLK.
- DSS.DISPC\_POL\_FREQ[13] IHS = 0

- The DISPC\_HSYNC signal is active high.
- DSS.DISPC\_POL\_FREQ[12] IVS = 0

### 1.2.1.2 SDI Serial Interface

This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

In the serial interface, the modules in the display subsystem path are the display controller and the SDI with its associated PLL. The display controller provides the required control signals to interface the memory frame buffer (either SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA to read the data from the system memory.

The SDI module is an additional display output mode that facilitates the connection of displays over relatively few conductors.

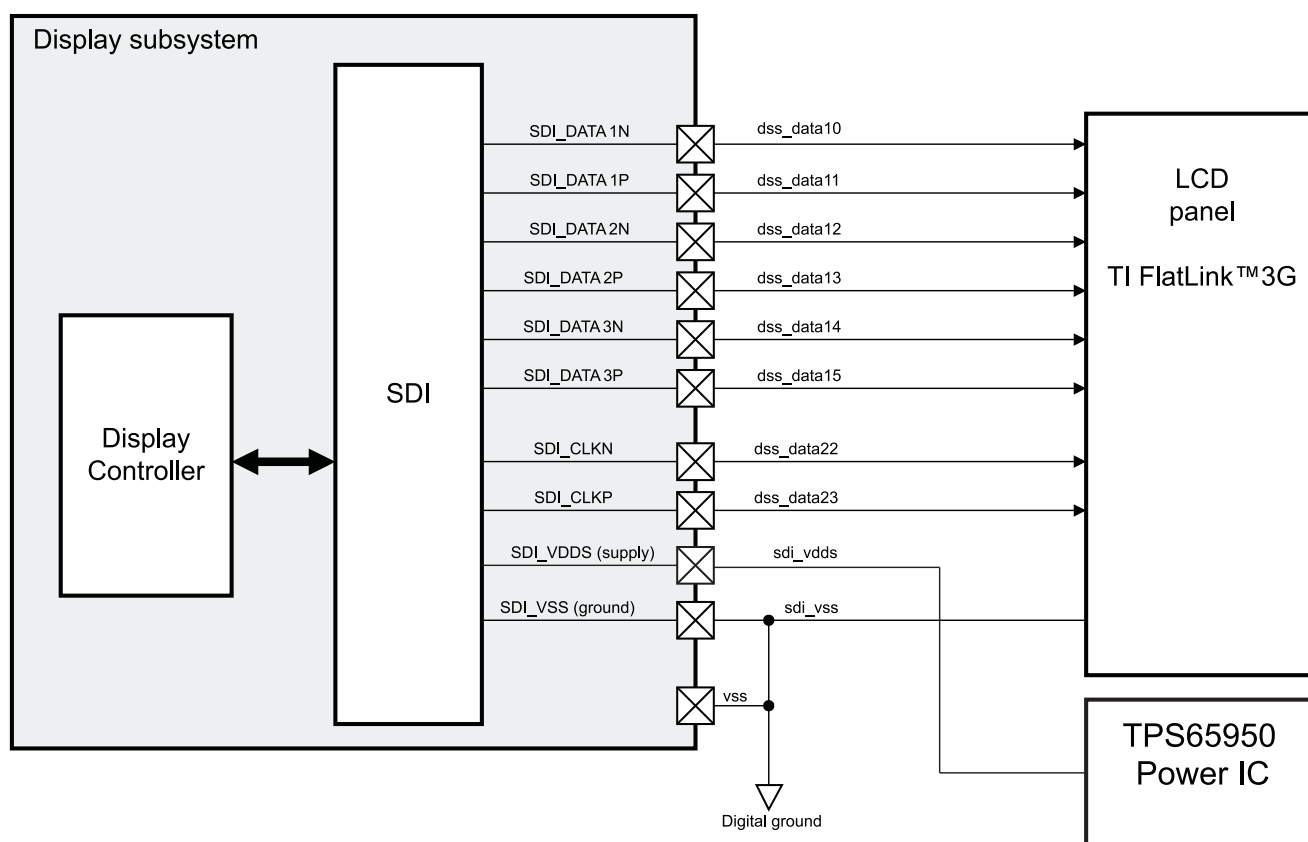

The SDI module implements the TI FlatLink™3G protocol and converts the conventional parallel display signals (including pixel data) from the display controller to serial form. Texas Instruments provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver - SN65LVDS302 receiver for 3-data pair, SN65LVDS304 receiver for 2-data pair and SN65LVDS306 receiver for 1-data pair. For more details on these devices, please visit [www.ti.com](http://www.ti.com).

The SDI module contains a PLL to multiply the pixel clock by an appropriate factor. The resulting serialized data is then transmitted on 1 to 3 differential data pairs and an additional clock pair that has a reference transition at the boundary between pixels.

**Note:** Only one 9-bit RFBI driven display can be run at the same time as the SDI.

Figure 1-33 shows a typical connection between the SDI module and a compliant panel display.

**Figure 1-33. Typical SDI Connection**

dss-031

### CAUTION

When routing the PCB, ensure that the connections between the OMAP device and the LCD panel meet TI FlatLink3G specifications.

#### Notes:

- The SDI pins are multiplexed in mode 1 with some LCD parallel pins. See the *System Control Module* chapter for more details on the pad multiplexing.
- The connection from the sdi\_vss pin of the device to the digital ground of the PCB must be as short as possible.
- The sdi\_vdds dedicated power supply is provided by a power IC. Texas Instruments provides a global solution with OMAP device associated to TPS65950 power IC. For more details on TPS65950 power IC, contact your TI representative.

**Table 1-7** describes the interface signals between the SDI module of the OMAP device and the LCD panel.

**Table 1-7. Interface Signals Between the SDI Module and LCD Panel**

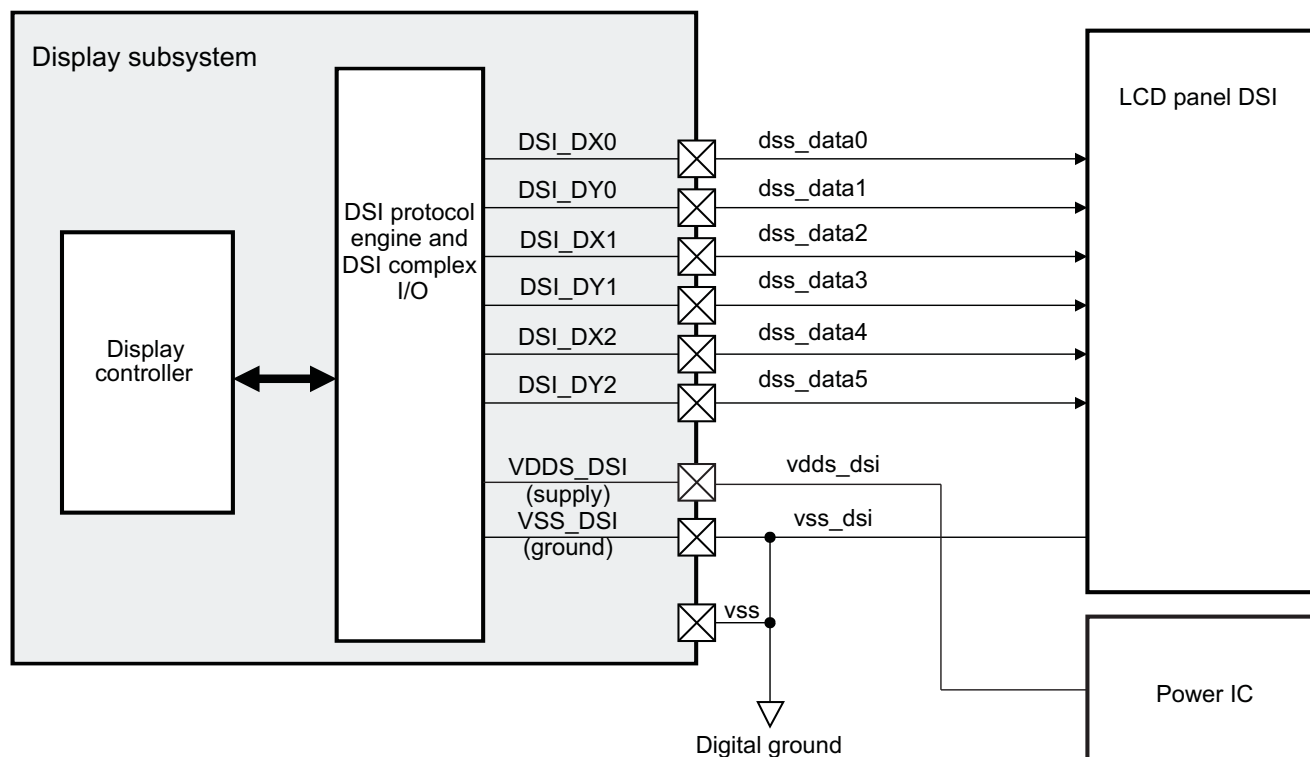

Signal Name	Type <sup>(1)</sup>	Description
SDI_DATA1N	O	First pair of differential data signals
SDI_DATA1P		
SDI_DATA2N	O	Second pair of differential data signals
SDI_DATA2P		
SDI_DATA3N	O	Third pair of differential data signals
SDI_DATA3P		
SDI_CLKN	O	Pair of differential clock signals
SDI_CLKP		
SDI_VDDS	PWR	Dedicated vdds power supply for SDI module
SDI_VSS	PWR	Dedicated vss ground for SDI module

<sup>(1)</sup> O=Output PWR=Power

### 1.2.1.3 DSI Serial Interface

Figure 1-34 shows a typical connection between the DSI modules and a compliant panel display.

**Figure 1-34. Typical DSI Connection**

dss-194

**Note:** The DSI pins are multiplexed in mode 1 with some LCD parallel pins. See the *System Control Module* chapter for more details on the pad multiplexing.

## 1.2.2 LCD Support With MIPI DSI 1.0 Protocol and Data Format

This section details briefly the MIPI DSI1.0 protocol and data format. For more details, see the MIPI DSI specification v1.0 (1.01.00r03) [2] with in addition the MIPI DSI Release note dated 26 July 2006 [13].

### 1.2.2.1 Physical Layer

Table 1-8 shows the DSI interface I/O.

**Table 1-8. I/O Description for DSI Serial Interface**

Signal Name		I/O <sup>(1)</sup>	Description	Value at Reset
dsi_dx0	line 1	I/O	Serial data/clock input/output	N/A
dsi_dy0				
dsi_dx1	line 2	I/O	Serial data/clock input/output	N/A
dsi_dy1				
dsi_dx2	line 3	I/O	Serial data/clock input/output	N/A
dsi_dy2				

<sup>(1)</sup> I/O = Input/Output

---

**Note:** Each serial line (line 1, line 2, and line 3) can be used as clock lane or data lane. All polarities are supported. The MIPI DSI 1.0 protocol requires at least one clock line and one data lane.

---

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- ULPS: Ultra-low power state used between two transmissions
- Off mode: Lane is off.

### 1.2.2.1.1 Data/Clock Configuration

From the device point of view, the DSI interface consists of six input/output signals representing three differential signals: The serial clock and one or two serial data. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The DSI transmitter in the host sends the data in-quadrature with the DDR clock in high speed mode otherwise the clock is extracted from the received data in low speed mode. The data is transmitted byte-wise least significant bit first.
- The clock signal carries the DDR clock signal in High speed transmission.
- Software users should configure the order of the data lanes to indicate the byte order while splitting the byte stream for each DSI\_PHY into bytes.

[Table 1-9](#) details all the DSI lanes configuration.

**Table 1-9. DSI Lane Configuration**

DSI_PHY Lane Configuration	Data/Clock Lane Position			Description
	1	2	3	
Mode CLK + DATA1	CLK	DATA1	Not used	Single Data Lane
	CLK	Not used	DATA1	
	DATA1	CLK	Not used	
	Not used	CLK	DATA1	
	DATA1	Not used	CLK	
	Not used	DATA1	CLK	
Mode CLK + DATA1 + DATA2	CLK	DATA1	DATA2	Two Data Lanes
	CLK	DATA2	DATA1	
	DATA1	CLK	DATA2	
	DATA2	CLK	DATA1	
	DATA1	DATA2	CLK	
	DATA2	DATA1	CLK	

**Notes:**

- The byte on Dn is sent before the byte on Dn+1, all the combinations of data and clock are supported through the programming of the DSS.DSI\_COMPLEXIO\_CFG1 register. The CLOCK\_POSITION and CLOCK\_POL fields configure which lane transmits the clock and define its polarity. Four fields (DATA1\_POSITION, DATA1\_POL, DATA2\_POSITION, and DATA2\_POL) configure the data lanes and their polarity. The DATA2\_POSITION field can be set to 0; in this case, only the data lane defined in the DATA1\_POSITION field is used, and data is transmitted on only one clock lane and one data lane.
- The configuration of the DSI complex I/O (number of data lanes, position, differential order) should not be changed while DSS.DSI\_CLK\_CTRL[20] LP\_CLK\_ENABLE bit is set to 1. In order for the hardware to take into account a new configuration of the complex I/O (done in DSS.DSI\_COMPLEXIO\_CFG1 register), it is recommended to follow this sequence: First set the DSS.DSI\_CTRL[0] IF\_EN bit to 1, then reset the DSS.DSI\_CTRL[0] IF\_EN to 0, then set DSS.DSI\_CLK\_CTRL[20] LP\_CLK\_ENABLE to 1 and finally set again the DSS.DSI\_CTRL[0] IF\_EN bit to 1. If the sequence is not followed, the DSI complex I/O configuration is unknown.
- Only DATA1 is bi-directional in command mode. The low-power received information is always sent by the display panel using DATA1. Since any lane of the DSI complex I/O can be configured as data lane DATA1, all lanes of the complex I/O are bi-directional

### 1.2.2.1.2 ULPS

Each lane can be put in ultra-low-power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane should be in stop state
- For data lanes, no data must be pending in the DSI module
- For data lane 1, no BTA should have been sent. The DSI module should have the control of the bus.

The control of each lane is independently controlled by the DSS.DSI\_COMPLEXIO\_CFG2 register.

### 1.2.2.2 Video Port (VP) Interface

**Note:** The signals described in this section are internal and not bounded outside the device. This section aims at helping the software user to understand the internal connections between the display controller (DISPC) and the DSI protocol engine.

[Table 1-10](#) summarizes the video interface signals. This interface is used to connect the display controller to the DSI protocol engine to send real time data stream. Note that only the active matrix timings are supported by DSI protocol engine. The HSYNC/VSYNC/DE/DATA signals are driven on rising or falling edge of the pixel clock (VP\_PCLK).

**Table 1-10. Video Interface for DSI Protocol Engine**

Signal Name	Type <sup>(1)</sup>	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23
VP_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during on clock period of VP_CLK
VP_DE	I	Data Enable
VP_STALL	O	The stall signal should be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode only, in that mode the HSYNC and VSYNC are not generated)

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

**Table 1-10. Video Interface for DSI Protocol Engine (continued)**

Signal Name	Type <sup>(1)</sup>	Description
VP_CLK	I	Display Controller internal clock. It is a free running clock. The VP_CLK is a divided clock from VP_PCLK.

**Notes:**

- The polarity of VP\_HSYNC and VP\_VSYNC are programmable by setting the DSS.DSI\_CTRL register
- The maximum frequency for VP\_CLK is 173 MHz at nominal voltage and 96 MHz at low voltage
- The clocks VP\_CLK and VP\_PCLK can have the same frequency.
- The number of bits to be captured on the video port is defined in the DSS.DSI\_CTRL[7:6] VP\_DATA\_BUS\_WIDTH field.
- VP\_DE is connected to the dss\_acbias signal in the display controller, and its polarity can be controlled by setting the DISPC\_POL\_FREQ[15] IEO bit.

The data received on the video port can be stored into the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the display controller
- There is no line buffer instantiated. In case there is no line buffer, the burst mode as defined as frequency burst mode, can not be used. Only the transparency burst mode is supported.

**Note:** The DSS.DSI\_CTRL[13:12] LINE\_BUFFER field defines the number of lines to be used for transferring data from the video port to the DSI link.

#### 1.2.2.2.1 Video Port Used for Video Mode

In case of video port used for video mode, the VP\_STALL is not used. [Table 1-11](#) indicates the active signals on the video port.

**Table 1-11. Video Interface in the Context of Video Mode**

Signal Name	Type <sup>(1)</sup>	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23
VP_PCLK	I	Pixel clock.
VP_DE	I	Data Enable
VP_CLK	I	It is a free running clock which is the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage <sup>(2)</sup> and 96 MHz at low voltage <sup>(2)</sup> .

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

<sup>(2)</sup> For more information, see the OMAP35xx DM Operating Condition Addendum.

Three video modes are available:

- No line buffer: The data received on the video port are directly output of the DSI port without buffering. The VP\_CLK should match the DSI high-speed (HS) clock to get the exact same throughput on the two ports (the two clocks should be generated using the same PLL, the subsystem should provide such configuration)
- One line buffer:
  - The data can be transferred as described in "No line buffer" configuration
  - the data are first stored into the line buffer, when all the data for one line are received; the DSI protocol engine sends the whole line. All the synchronization packets occur at the same time as previous mode. Only the time when RGB packets are sent is delayed.

- Two line buffers:
  - The data can be transferred as described in "one line buffer" configuration
  - One line is stored when the second line is output on the DSI port. It allows burst capability. The synchronization packets are not modified when bursting the RGB packets. While receiving the first line of the frame, there is no RGB packets sent since the line buffers are empty. To send the last line of the frame, a dummy line should be provided by the display controller to flush the line buffers.

---

**Note:** If more active lines are received on the video port than the number defined in the DSS.DSI\_VM\_TIMING3[15:0] VACT field, the extra lines are discarded by the DSI protocol engine. These lines are considered as blanking lines.

---

[Figure 1-35](#), [Figure 1-36](#) and [Figure 1-37](#) show these three video modes.

**Figure 1-35. DSI Video Mode Without Burst (No-Line Buffer)**

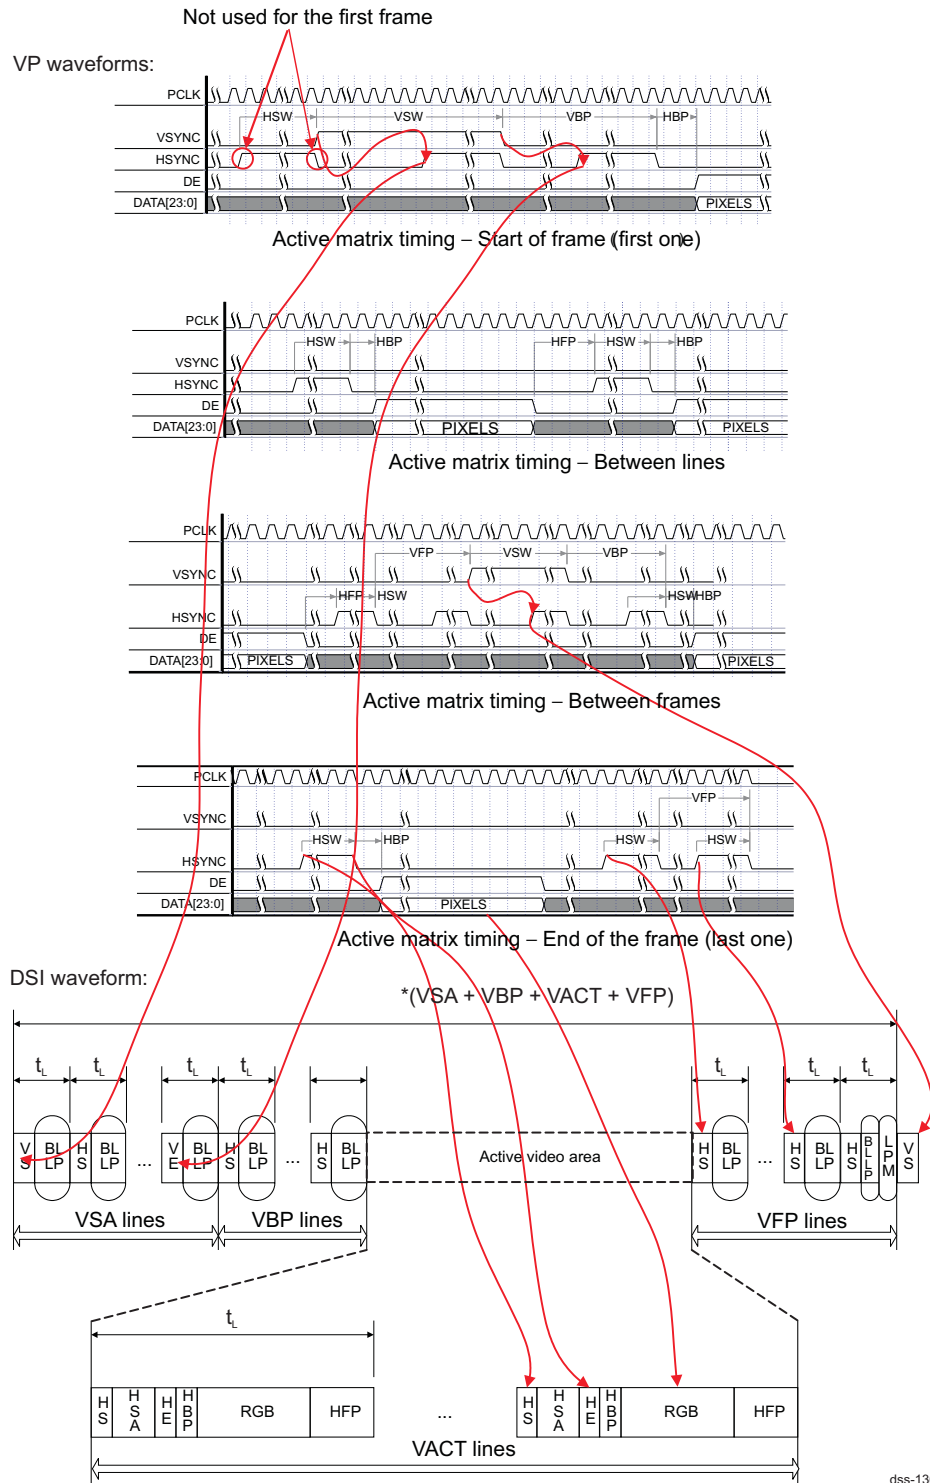

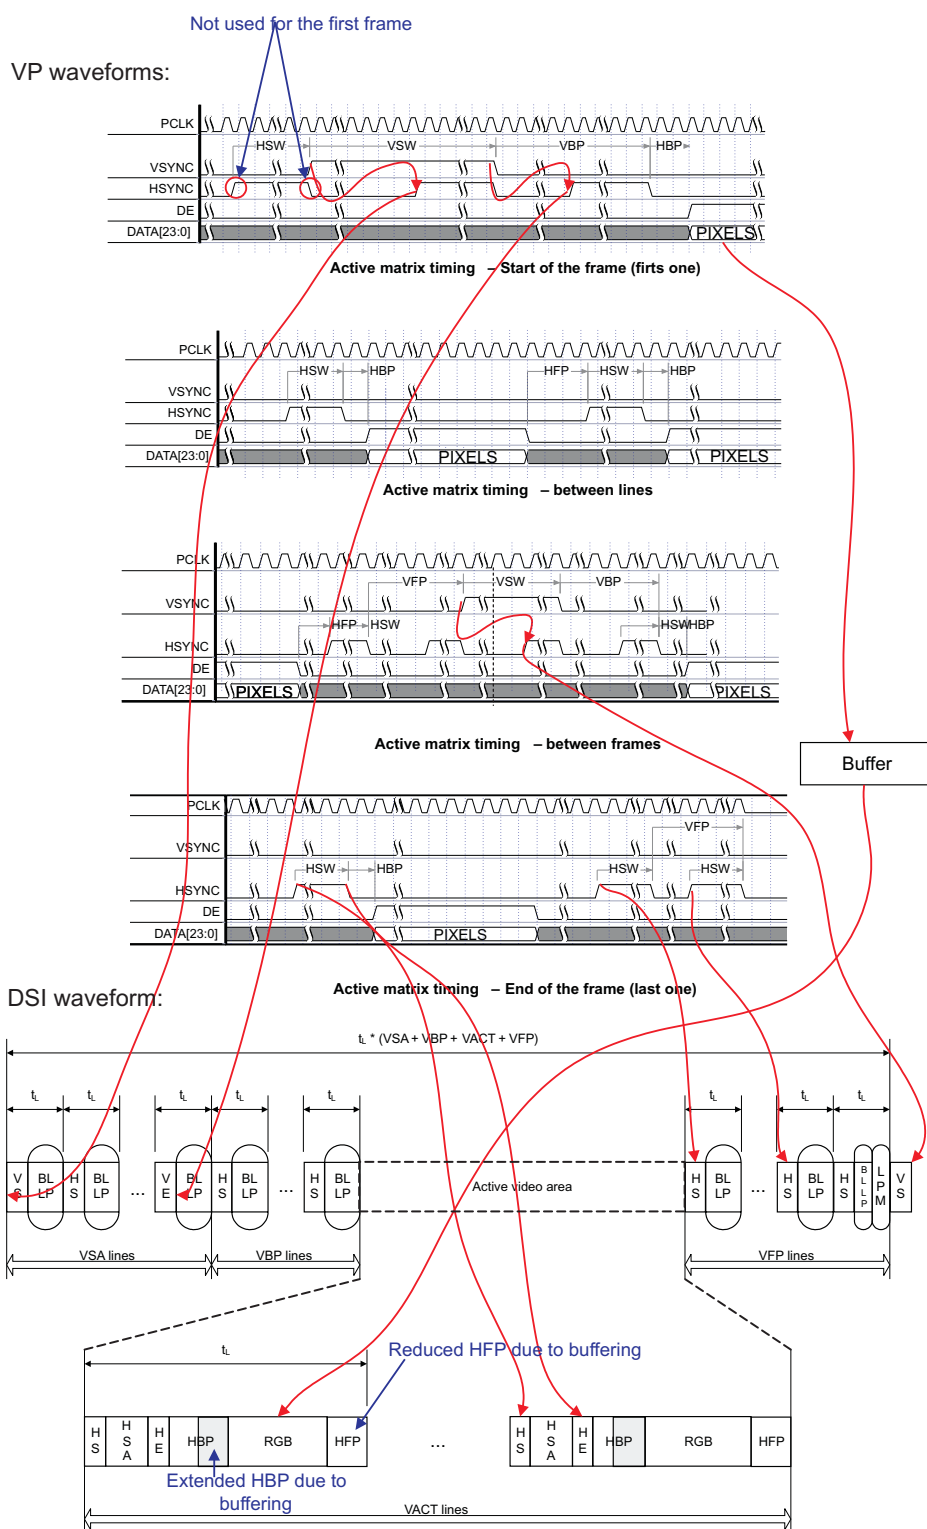

Figure 1-36. DSI Video Mode Without Burst (One-Line Buffer)

dss-137

Not used for the first frame

The timing diagram illustrates the relationship between the video input signals and the pixel data transfer. The signals shown are PCLK (Pixel Clock), VSYNC (Vertical Sync), HSYNC (Horizontal Sync), DE (Data Enable), and DATA[23:0] (Pixel Data). The diagram shows the sequence of pixel data transfer from the input to the output, with red arrows indicating the flow of data. The output data is shown as a sequence of pixels, with the first pixel being the first pixel of the first line, and the last pixel being the last pixel of the last line.

**Active matrix timing – Start of the frame (first one)**

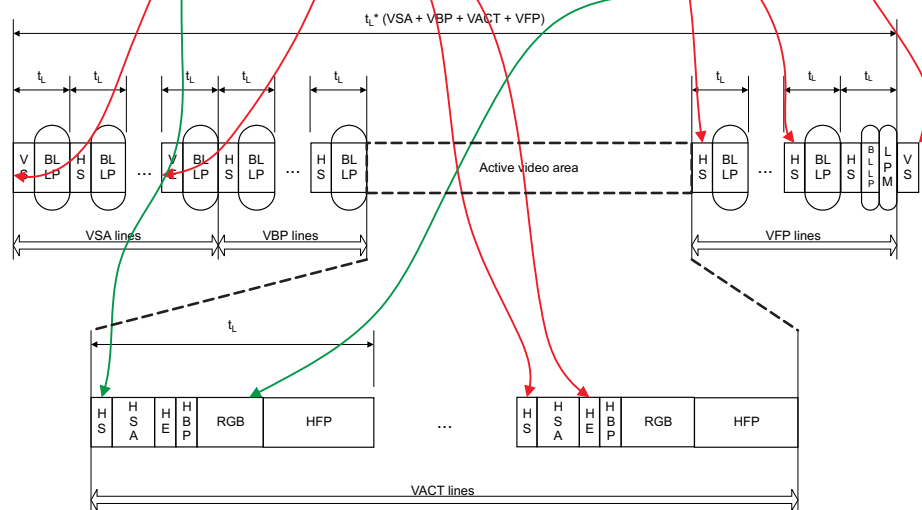

~~Active matrix timing – Between lines~~

### Active matrix timing – Between frames

Dummy line  
(not stored in the buffer)

**Active Matrix Timing – End of the frame (last one)**

DSI waveform:

47

**Note:** In the figures above:

- When HSync start and Hsync end short packets are not generated (HSA does not exist), HBP signal must be different than 0.
- The software should ensure that VBP is always defined in such a way that there is at least one HSYNC during VBP.
- In blanking low-power mode (BL-LP), two options are possible:
  - The lane remains in ULPS, and the DSI\_CTRL[20] BLANKING\_MODE bit is set to 0x0.
  - Dummy bytes are sent during LP with the DSI\_CTRL[20] BLANKING\_MODE bit set to 0x1; the number of sent bytes is determined by the DSI\_VM\_TIMING6[15:0] BL\_LP\_INTERLEAVING bit field.

In case the signal VP\_DE is not asserted during enough VP\_PCLK cycles to be able to capture the number of bytes defined in the word count of the header, the module must send the valid data received on the video port followed by bytes of 0s to match the required number of bytes to transmit. The VP\_PCLK should be present during all extra cycles where the DSI protocol engine is expecting pixels.

If the VP\_DE signal is asserted during too many VP\_PCLK cycles, the module should stop capturing the data on the video port while the number of bytes to capture as defined in the word count field of the header is reached.

The HS should check that the received synchronization events on video port (VSYNC and HSYNC) are inside the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out of sync should be generated and the interface should be disabled (DSS.DSI\_CTRL[0] IF\_EN bit is automatically reset by hardware). The unsynchronization window is defined by the DSS.DSI\_VM\_TIMING2[27:24] WINDOW\_SYNC field.

#### 1.2.2.2.2 Video Port Used on Command Mode

In case of video port used for command mode, the VP\_HSYNC, VP\_VSYNC and VP\_DE signals are not used. [Table 1-12](#) indicates the active signals on the video port.

**Table 1-12. Video Interface in the Context of Command Mode**

Signal Name	Type <sup>(1)</sup>	Description
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23
VP_PCLK	I	One pulse is generated every time new data is output on the data bus
VP_STALL	O	The stall signal should be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode only, in that mode the HSYNC and VSYNC are not generated)
VP_CLK	I	Display controller internal clock: It is a free running clock which is the display controller functional clock. The maximum frequency is 173MHz at nominal voltage and 96 MHz at low voltage.

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

**Note:** The stall signal should be deasserted to receive pixel and asserted to stop receiving pixel.

[Figure 1-38](#) and [Figure 1-39](#) shows the VP\_STALL signal assertion and deassertion on both rising and falling edges.

**Note:** In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC\_CONTROL[11] STALLMODE bit to 1

**Figure 1-38. Stall Timing With Pixel on Rising Edge**

dss-187

**Figure 1-39. Stall Timing With Pixel on Falling Edge**

dss-188

To stop the transfer the VP\_STALL signal must be asserted when the last data is output. The data can be output on the rising or falling edge of the VP\_PCLK through some registers in the Display Controller module. The case with data output on falling edge of VP\_PCLK is supported by the DSI protocol engine.

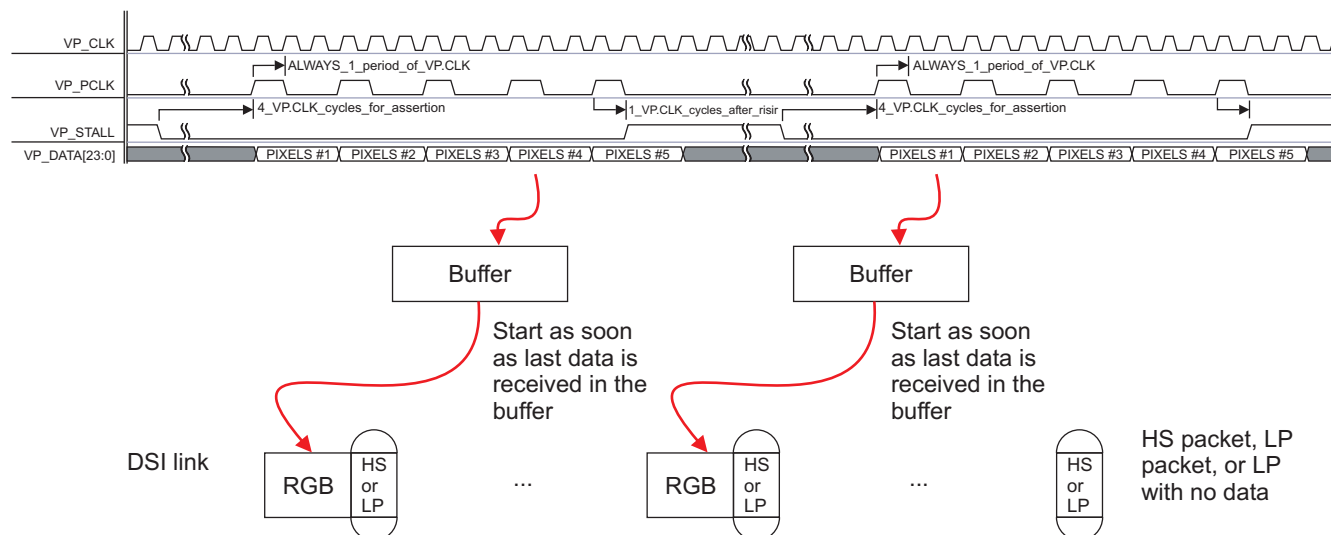

The clock VP\_PCLK is generated from VP\_CLK, these two clocks are balanced. Assertion and deassertion of VP\_PCLK is done on rising edge of the VP\_CLK. The width of the VP\_PCLK pulse depends on the configuration of the clock divisor in the display controller (DSS.DISPC\_DIVISOR[7:0] PCD field). In the DSI protocol engine, the information is defined in the DSS.DSI\_CTRL[4] VP\_CLK\_RATIO bit and should be aligned with the display controller configuration.

The deassertion of the VP\_STALL signal should occur at least 4 VP\_CLK cycles before assertion of VP\_PCLK. The assertion of VP\_STALL should occur one cycle VP\_CLK after deassertion of VP\_PCLK for the last pixel to be transferred. The VP\_CLK clock is generated by the Display controller under software control. It can be kept running between VP\_STALL assertion and deassertion period.

The word count (WC) defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register for the virtual channel associated with the video port, indicates the number of bytes to receive (one line or two lines can be used depending on the WC and size of the line buffer). The total size defined in the WC of the header register can not exceed the size of the line buffer multiplied by the number of buffer lines.

The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined DSS.DSI\_CTRL[7:6] VP\_DATA\_BUS\_WIDTH field.

Figure 1-40 shows the data flow for command using the video port.

**Figure 1-40. Data Flow for Command Mode Using Video Port**

dss-139

Two command modes are available:

- One line buffer: The data are stored in the line buffer before being sent
- Two line buffers: The two lines are used if the word count defined in the DSS.DSI\_VCN\_LONG\_PACKET\_HEADER register is bigger than the line size otherwise one line buffer is used.

**Note:** In command mode, the video port can only be used in one or two line buffer configuration. The no-line buffer configuration is not allowed.

The packets can be sent using High-Speed or Low-Speed.

**Note:** The DCS command in the payload can be inserted automatically using the DSI\_CTRL[24] DCS\_CMD\_ENABLE bit. If TE is used, hardware automatically inserts the DCS Write Start command for the first packet of the frame transfer and the DCS Write Continue command for all subsequent packets.

### 1.2.2.2.3 Burst Mode

When the burst mode is enabled, the video port receives data from the display controller at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double line buffer of 1024 x 24-bit pixels maximum). The read speed of the line can be the double of the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. The burst mode is using a dual-line buffer.

The DSI port can output data from one line buffer while the second one is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the whole video port line is transferred into a line buffer. The switch is controlled by the VP\_HS signal on the video port side and by internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

**Note:** The line buffers are used to store the pixels only. The synchronization codes are not stored in the line buffers. They should be sent according to the video port timings.

### 1.2.2.3 Multilane Layer

Peripherals typically do not have substantial bandwidth requirements for returning data to the host processor. To keep designs simple and improve interoperability, all DSI-compliant systems should only use Lane 1 in LP Mode for returning data from a peripheral to the host processor.

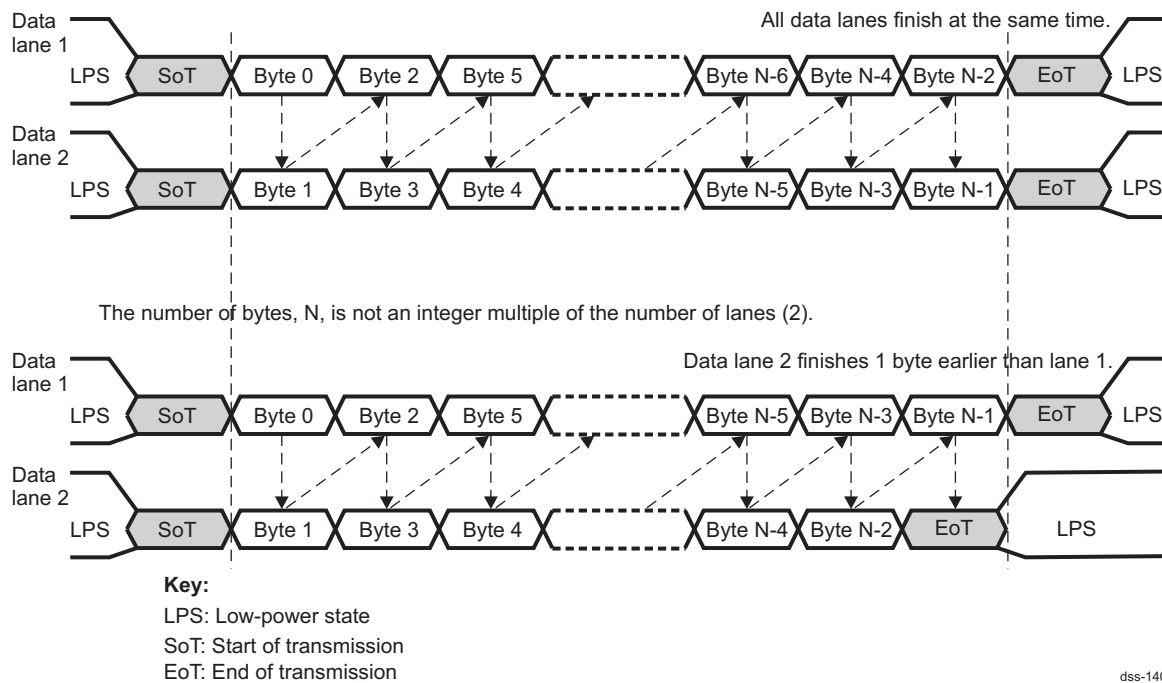

#### 1.2.2.3.1 SoT and EoT in Multilane Configurations

Since a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the Lane Management layer, as it buffers up the final set of less-than-N bytes, deasserts its "valid data" signal into all lanes for which there is no further data. Although all Lanes start simultaneously with parallel SoTs, each lane operates independently and may complete the HS transmission before the other lanes, sending an EoT one cycle (byte) earlier.

#### 1.2.2.3.2 Lane Splitter

The lane splitter can split the byte stream into 2 lanes (for 1 lane, the splitter is bypassed). [Figure 1-41](#) and [Figure 1-42](#) show the byte position into each serial link for 1, and 2 data lane configuration. The byte stream starts always from the lane 1. It finishes on one of the lanes depending on the number of bytes to send and the number of lanes. The splitter module is only used when packets are sent using High Speed mode (HS). In Low Power mode (LP), only one data lane is used (Lane 1).

**Figure 1-41. Two Data Lane Configuration**

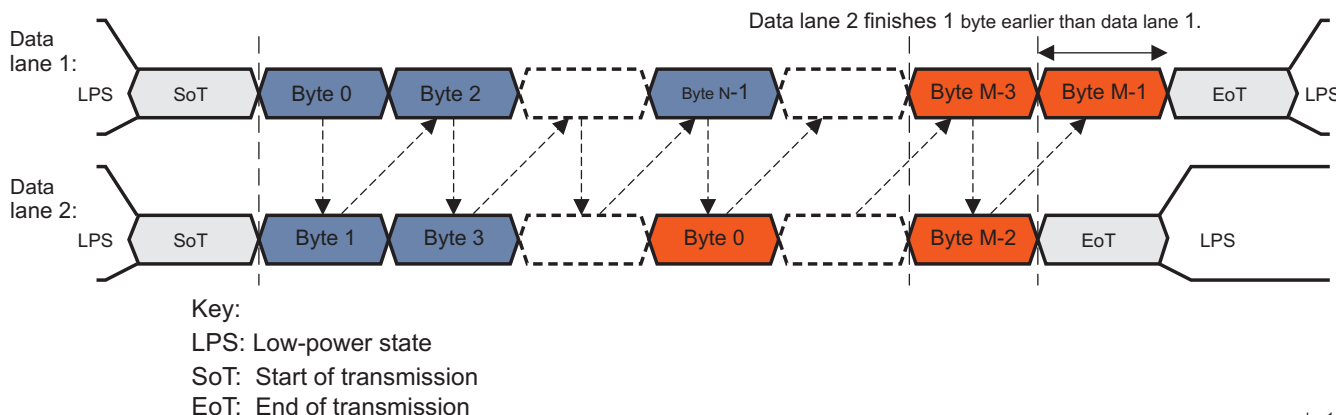

**Figure 1-42. One Data Lane Configuration**

In case of back-to-back packets, the byte stream is considered by the splitter module as a single packet. [Figure 1-43](#) shows the example of two packets sent back to back. N bytes for the first packet and M bytes for the second one.

**Figure 1-43. Two Packets Using Two-Data Lane Configuration (Example)**

dss-142

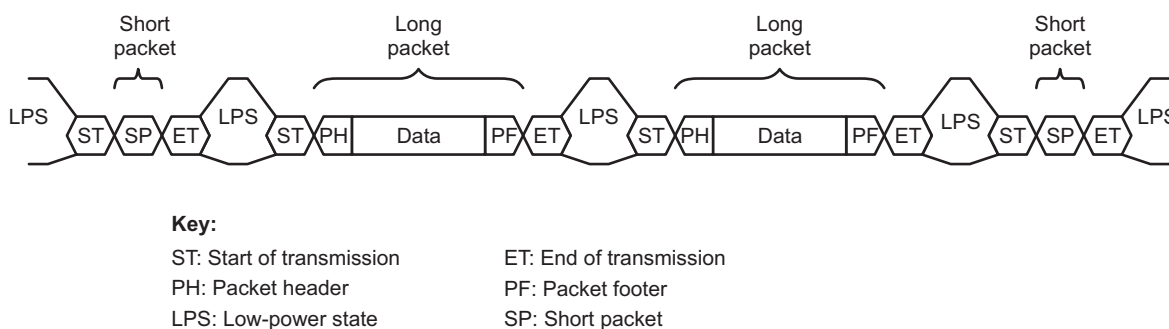

#### 1.2.2.4 Protocol Layer

The low level protocol (LLP) is a byte oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the physical layer. Packets can be sent using High speed mode or Low speed mode. It is selected through DSI registers. The feature set of the DSI protocol layer is:

- Transport of arbitrary data (Payload independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame start, frame end, line start and line end information
- Descriptor for the type, pixel depth and format of the application-specific payload data
- Error Correction Code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit Checksum Code for error detection

[Figure 1-44](#) shows the protocol layer with short and long packets.

**Figure 1-44. Protocol Layer With Short and Long Packets**

dss-143

##### 1.2.2.4.1 Short Packet

[Figure 1-45](#) shows the structure of the Short packet. A Short packet should contain an 8-bit Data ID followed by two command or data bytes and an 8-bit ECC; a Packet Footer should not be present. Short packets should be four bytes in length. The Error Correction Code (ECC) byte allows single-bit errors to be corrected and 2-bit errors to be detected in the Short packet.

**Figure 1-45. Short Packet Structure**

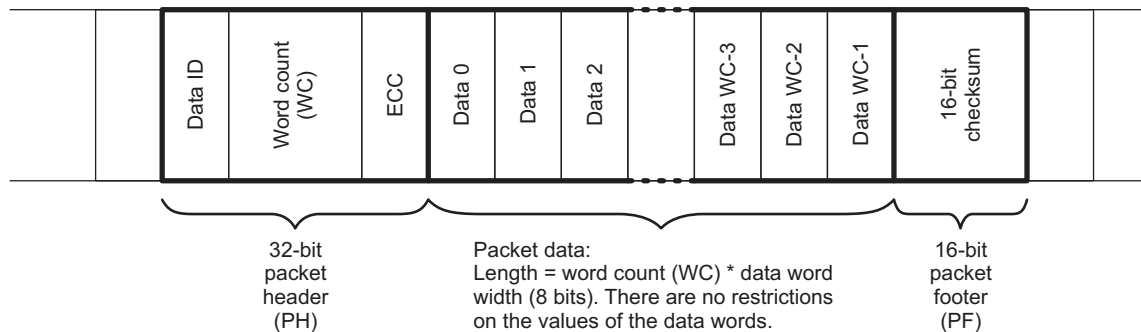

dss-144

**Note:** The short packets can be sent in Low power mode or in High speed mode.

#### 1.2.2.4.2 Long Packet

Figure 1-46 shows the structure of the Low Level Protocol Long Packet. A long packet should consist of three elements: A 32-bit packet header (PH), an application-specific Data Payload with a variable number of bytes, and a 16-bit Packet Footer (PF). The packet header is further composed of three elements: An 8-bit Data Identifier, a 16-bit Word Count, and 8-bit ECC. The Packet Footer has one element, a 16-bit checksum. Long packets can be from 6 to 65,541 bytes in length.

**Figure 1-46. Long Packet Structure**

dss-145

- The Data Identifier defines the Virtual Channel for the data and the Data Type for the application specific payload data.
- The Word Count defines the number of bytes in the Data Payload between the end of the packet header and the start of the Packet Footer. Neither the packet header nor the Packet Footer should be included in the Word Count.
- The Error Correction Code (ECC) byte allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header. This includes both the Data Identifier and Word Count fields.

After the end of the packet header, the receiver reads the next Word Count \* bytes of the Data Payload. Within the Data Payload block, there are no limitations on the value of a data word, that is, no embedded codes are used. Once the receiver has read the Data Payload it reads the Checksum in the Packet Footer. The host processor should always calculate and transmit a Checksum in the Packet Footer. Peripherals are not required to calculate a Checksum. Also note the special case of zero-byte Data Payload: If the payload has length 0, then the Checksum calculation results in (0xFFFF). If the Checksum is not calculated, the Packet Footer should consist of two bytes of all zeros (0x0000). In the generic case, the length of the Data Payload should be a multiple of bytes. In addition, each data format may impose additional restrictions on the length of the payload data, e.g. multiple of four bytes. Each byte is transmitted least significant bit first. Payload data may be transmitted in any byte order restricted only by data format requirements. Multibyte elements such as Word Count and Checksum should be transmitted least significant byte first.

**Note:** The long packets can be sent in Low power mode or in High speed mode.

### 1.2.2.4.3 Data Identifier

The Data Identifier byte contains the Virtual Channel Identifier (VC) value and the Data Type (DT) value as illustrated in [Figure 1-47](#). The Virtual Channel Identifier is contained in the two MS bits of the Data Identifier Byte. The Data Type value is contained in the six LS bits of the Data Identifier Byte. DI[7:6]: These two bits identify the data as directed to one of four virtual channels. DI[5:0]: These six bits specify the Data Type.

**Figure 1-47. Data Identifier Structure**

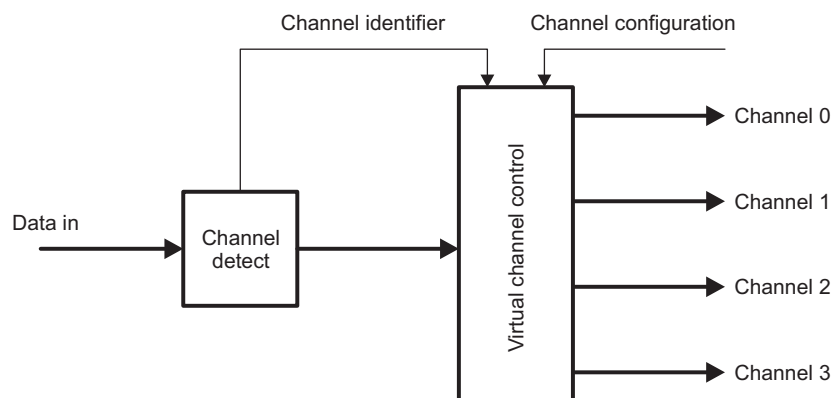

dss-146

### 1.2.2.4.4 Virtual Channel ID - VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data, using the Virtual Channel ID field of the header for packets targeted at different peripherals. The Virtual Channel ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Note that packets sent in a single transmission each have their own Virtual Channel assignment and can be directed to different peripherals. The virtual channel ID is defined in the DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER and DSS.DSI\_VCn\_LONG\_PACKET\_HEADER registers for respectively short and long packets. It should not be modified by hardware. There is one set of registers for each virtual channel. Each set of registers defines the characteristics of the traffic between the host and the display associated to the virtual channel.

[Figure 1-48](#) shows the virtual channel controller.

**Figure 1-48. Virtual Channel Controller**

dss-147

#### 1.2.2.4.5 Data Type Field DT[5:0]

The Data Type field specifies whether the packet is a Long or Short packet type and the packet format. The Data Type field, along with the Word Count field for Long packets, informs the receiver of how many bytes to expect in the remainder of the packet. This is necessary because there are no special packet start /end sync codes to indicate the beginning and end of a packet. This permits packets to convey arbitrary data, but it also requires the packet header to explicitly specify the size of the packet.

#### 1.2.2.4.6 Pixel Data Formats in Video Mode

The host can send different pixels format in video mode. [Table 1-13](#) summarizes the pixel formats supported by the DSI interface in video mode.

**Table 1-13. Pixel Data Format in Video Mode**

Mode	Description
RGB888 (using 24-bit container)	RGB888
RGB666 (using 24-bit container)	RGB666
RGB666 (18-bit packet using 18-bit container)	RGB666_PACKET
RGB565 (using 16-bit container)	RGB565

#### 1.2.2.4.7 Synchronization Codes

Each frame can be identified by two synchronization codes: One for the start of vertical synchronization pulse (VSSC) and one for the end of the vertical synchronization pulse (VSEC). Each line can be identified by two synchronization codes: One for the start of horizontal synchronization pulse (HSSC) and one for the end of the horizontal synchronization pulse (HSEC). The synchronization events may not be required by the display (peripheral): They are optional. Users can program which sync events are generated to the display from the timings received from the display controller in video mode. When data are received on the L4 interconnect slave port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L4 interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the display controller to receive the synchronization events to generate automatically the short synchronization packets to the peripheral. When the DSI protocol engine detects that the VSYNC signal from the display controller transition from inactive to active state, the VSSC short packet replaces the following HSSC corresponding to the following HSYNC synchronization short packet (if the generation is enabled). When the transition from active to inactive state is detected, the VSEC short packet is generated (if the generation is enabled) replacing the HSSC synchronization packet corresponding to the following HSYNC. When the DSI protocol engine detects that the HSYNC signal from the display controller transition from inactive to active state, the HSSC short packet is generated (if the generation is enabled). When the transition from active to inactive state is detected, the HSEC short packet is generated (if the generation is enabled). For the first frame, any HSYNC and data received on the video port prior to the first VSYNC should be ignored. Since the first VSYNC sent to the display is also recognized as a HSYNC for the first line, there should not be any HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses the short packets. [Table 1-14](#) summarizes the 6-bit data type synchronization code values.

**Table 1-14. Synchronization Codes**

Synchronization Code	Value	Comments
V Sync. Start Code (VSSC)	0x1	Optional
V Sync. End Code (VSEC)	0x11	Optional
H Sync. Start Code (HSSC)	0x21	Optional
H Sync. End Code (HSEC)	0x31	Optional

### 1.2.2.4.8 Blanking

To keep the DSI link in HS state while using the video mode, during blanking periods, the long Blanking packets are sent to the display. The DSS.DSI\_VM\_TIMINGi (i between 1 and 7) registers define the size of the long Blanking packets after:

- Horizontal Sync Start code (short packet)
- Horizontal Sync End code(short packet)
- Vertical Sync Start code(short packet)
- Vertical Sync End code(short packet)
- Pixels (long packet)

Table 1-15 defines the short packet values for the synchronization packets:

**Table 1-15. Sync Short Packet Values**

Virtual Channel ID	Sync code	Header (1st byte)	Header (2nd byte): Data Field LSB	Header (3rd byte): Data Field MSB	Header (ECC)
0x0	0x1	0x1	0x0	0x0	See note following this table
	0x11	0x11			
	0x21	0x21			
	0x31	0x31			
0x1	0x1	0x41			
	0x11	0x51			
	0x21	0x61			
	0x31	0x91			
0x2	0x1	0x81			
	0x11	0x81			
	0x21	0xA1			
	0x31	0xB1			
0x3	0x1	0xC1			
	0x11	0xD1			
	0x21	0xC1			
	0x31	0xF1			

#### Notes:

- If the ECC is enabled by setting the DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit to 1 for the virtual channel in video mode, the ECC value is then calculated otherwise 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSS.DSI\_VCn\_CTRL[7] CS\_TX\_EN bit to 1 for the virtual channel in video mode, the Check-sum value is then calculated otherwise 0x00 is used for the blanking long packets.
- In other cases, when the DSS.DSI\_VCn\_CTRL[7] CS\_TX\_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets except when the header is provided by register since the ECC field is available in the register. It can be used to generate invalid ECC value when the header is provided by register.

The link (lane(s) and clock separately) can be put in ULPS mode. While using the blanking values defined above, the packets (short and long packets) are considered in HS mode.

The timing parameters: VSA, VBP, VFP, HSA, HBP, HFP, VACT and  $t_L$  are defined in the

DSS.DSI\_VM\_TIMINGx (x between 1 and 7) register. HSA, HBP, HFP, and  $t_L$  are defined using the byte clock unit (PPI Byte clock) and also in Low power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined in term of number of lines. When the HS Blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (taking in account the 4-byte header and the 2-byte check sum)

The configuration of the display controller timing generator should be used when the display controller timings are used to generate the DSI HS video mode transfer.

Special care should be taken in the case of the last line of the frame. The LPS transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period can not be used for sending any data from TX FIFO. When the blanking period starts with one HS packet from one VC, it can only be followed by another HS packet from the same VC or by trigger (BTA for example). When there is no more HS data to send for this VC, the lane is in LPS. When the blanking period starts with one LP packet from one VC, it can only be followed by another LP packet from the same VC or another VC or by trigger (BTA for example) or by extra LPNULL packets. If the trigger has been sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LP mode or the trigger has been sent, the lane is put in LPS. If the lanes should be kept in HS mode during blanking periods (except for last blanking period of the frame), the HS blanking packets should be used. In case one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in ULPS.

**Figure 1-49. DSI Video Mode: Nonburst Transfer With VE and HE**

dss-148

**Figure 1-50. DSI Video Mode: Nonburst Transfer Without VE and HE**

dss-149

**Note:** HSA timing is not used and does not need to be programmed when HE short packet is not generated.

Figure 1-51. DSI Video Mode: Burst Transfer Without VE and HE

dss-150

**Note:** HSA timing is not used and does not need to be programmed when HE short packet is not generated.

In the last two figures, if HSync Start end packet is not generated (HSA does not exist), HBP should be different than 0.

### 1.2.2.4.9 Frame Structures

Figure 1-52 shows the general frame structure.

#### 1.2.2.4.10 Virtual Channels

The DSI protocol layer transports virtual channels. The purpose of virtual channels is to separate different data flows, which are interleaved in a same data stream. Each virtual channel is identified by a unique channel identification number in the header of the packet. The channel identification number is encoded in the 2-bit code. The DSI protocol engine determines the channel identifier number to be used for generating the packet header and multiplexes the interleaved data streams. The DSI protocol engine supports multiple concurrent virtual channels: Up to 4. [Table 1-16](#) summarizes the virtual channel values used for each channel.

**Table 1-16. Virtual Channel Values**

Virtual Channel Number	Value
Virtual Channel 0	0x0
Virtual Channel 1	0x1
Virtual Channel 2	0x2
Virtual Channel 3	0x3

In the case of multiple displays connected to the single DSI port on the host, a hub may be used to root the data stream to the appropriate display based on the virtual channel ID. Typically, virtual channel id 0x0 is used for the primary display and 0x1 for the secondary. The hub may have its own virtual channel id in order to provide communication capability between the host and the hub.

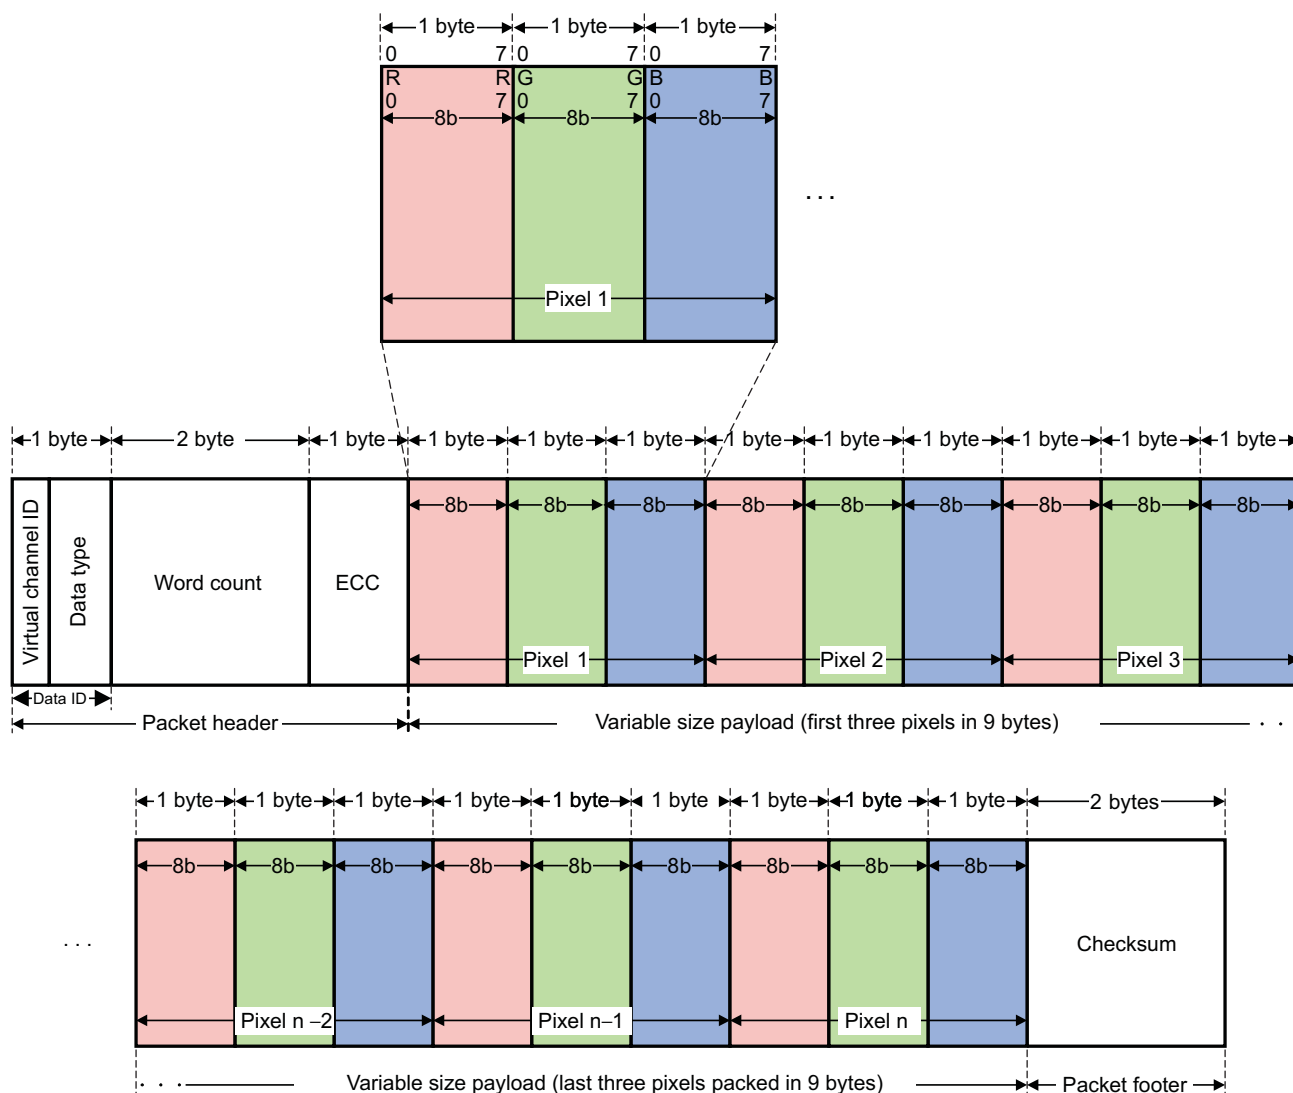

#### 1.2.2.5 Pixel Data Formats

This section summarizes how the DSI supported pixel data formats in case of video mode are transmitted over the serial interface. For pixel formats in case of command mode, refer to MIPI DCS document. The DSI protocol engine is able to cope with all data formats given that the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

### 1.2.2.5.1 24 Bits per Pixel - RGB Color Format, Long Packet

Figure 1-55 shows the RGB888 format.

**Figure 1-55. 24 bits per Pixel RGB Color Format, Long Packet**

dss-154

Packed Pixel Stream 24-Bit Format is a Long packet. It is used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes and a two-byte Checksum. The pixel format is red (8 bits), green (8 bits) and blue (8 bits), in that order. Each color component occupies one byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first, the MSB last.

### 1.2.2.5.2 18 Bits per Pixel (Loosely Packed) - RGB Color Format, Long Packet

Figure 1-56 details the RGB666 format.

Figure 1-56. 18 Bits per Pixel (Loosely Packed) RGB Color Format, Long Packet

dss-155

In the 18-bit Pixel Loosely Packed format, each R, G, or B color component is six bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires three bytes as it is transmitted across the Link. This requires more bandwidth than the packed format, but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the Link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes and a two-byte Checksum. The pixel format is red (6 bits), green (6 bits) and blue (6 bits) in that order. Within a color component, the LSB is sent first, the MSB last.

### 1.2.2.5.3 18 Bits per Pixel (Packed) - RGB Color Format, Long Packet

Figure 1-57 details the RGB666\_PACKED format.

**Figure 1-57. 18 Bits per Pixel (Packed) RGB Color Format, Long Packet**

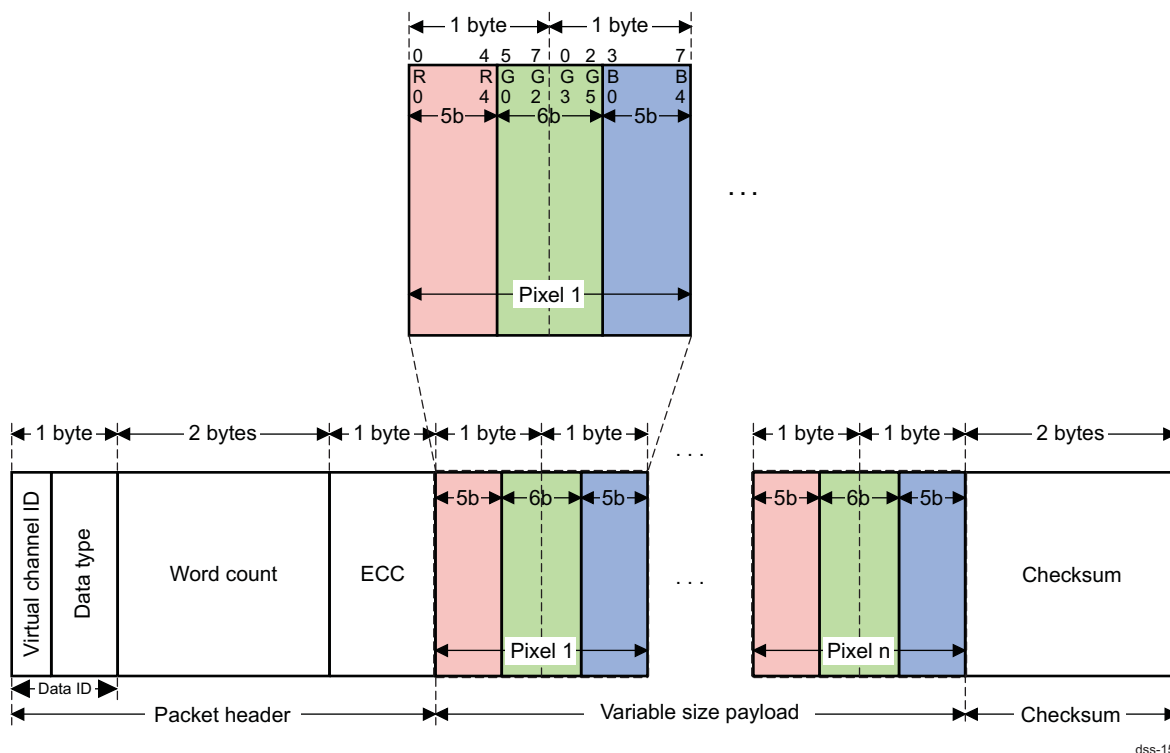

dss-156

Packed Pixel Stream 18-Bit Format (Packed) is a Long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes and a two-byte Checksum. Pixel format is red (6 bits), green (6 bits) and blue (6 bits), in that order. Within a color component, the LSB is sent first, the MSB last. With this format, it is strongly recommended that the total line width be a multiple of four pixels (nine bytes).

#### 1.2.2.5.4 16 Bits per Pixel - RGB Color Format, Long Packet

Figure 1-58 details the RGB565 format.

**Figure 1-58. 16 Bits per Pixel RGB Color Format, Long Packet**

Packed Pixel Stream 16-Bit Format is a Long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes and a two-byte checksum. Pixel format is five bits red, six bits green, five bits blue, in that order. Note that the "Green" component is split across two bytes. Within a color component, the LSB is sent first, the MSB last.

### 1.2.3 LCD Output With TI FlatLink3G Data Format for the SDI Module

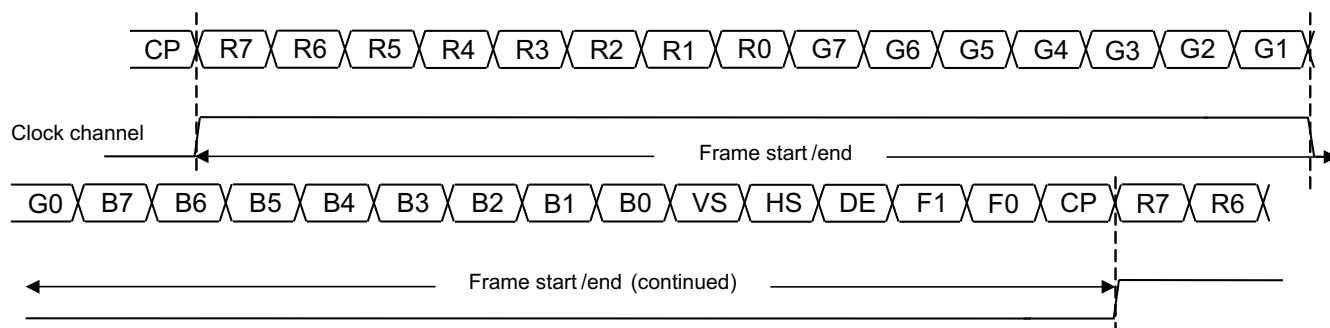

This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

The parallel-to-serial conversion of the 24-BPP pixel data depends on the number of data channels in use.

Figure 1-59 through Figure 1-61 summarize the pixel order for each data format of the TI FlatLink3G LCD panel.

The following apply to Figure 1-59 through Figure 1-61:

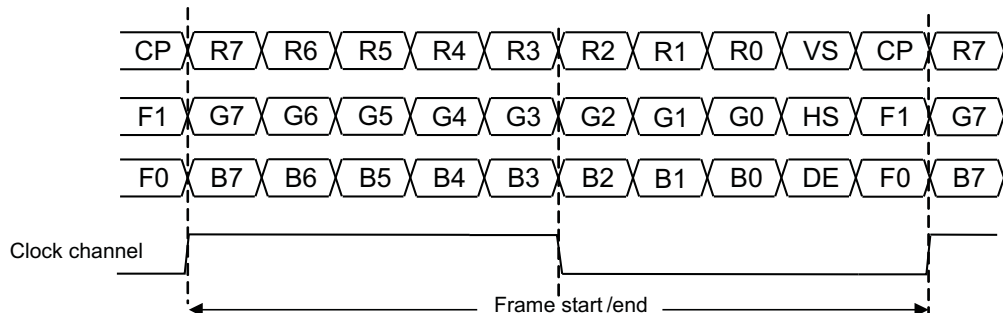

- VS: Vertical synchronization
- HS: Horizontal synchronizations
- DE: Data enable
- CP: Pixel parity. Parity of the whole 30-bit data is odd
- F1, F0: Reserved bits for the TI FlatLink3G protocol
- Clock Channel: Differential clock signal between SDI\_CLKP and SDI\_CLKN

**Figure 1-59. 24 Bits Per Pixel With One Data Channel**

dss-032

**Figure 1-60. 24 Bits Per Pixel With Two Data Channels**

dss-033

**Figure 1-61. 24 Bits Per Pixel With Three Data Channels**

dss-034

**Note:** The range of the data rates permitted is 120 Mbps per pair minimum (4 MHz pixel clock, one data pair) to 650 Mbps per pair maximum (65 MHz pixel clock, three data pairs).

### 1.2.4 TV Display Support

The TV display path includes the following modules:

- Display controller
- Video encoder
- Dual 10-bit DAC with video amplifiers

The display controller module receives synchronization signals from the video encoder and synchronously sends pixel data to the video encoder with these signals. The digital output of the display controller is always a 24-bit RGB value based on a pixel request from the video encoder.

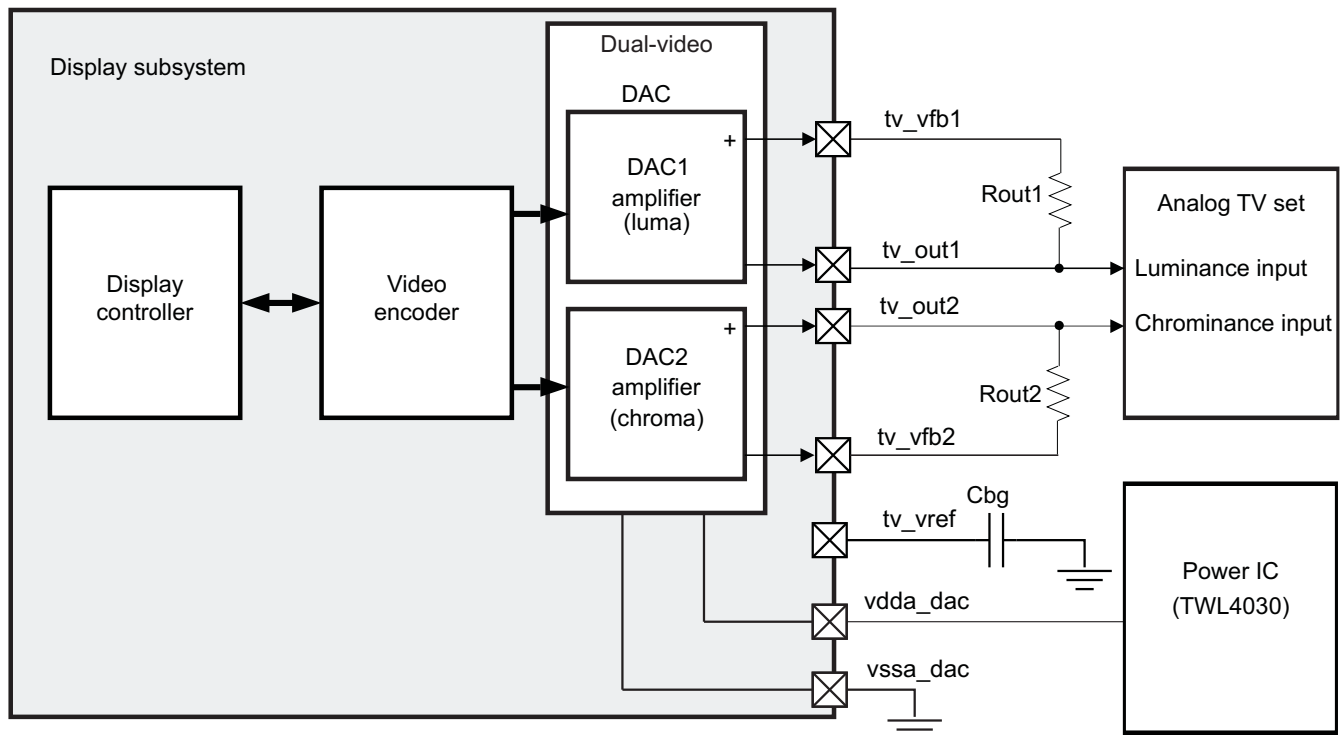

The video encoder converts RGB video signals to conform to the NTSC/PAL standard analog video. The video encoder includes an integrated synchronization signal generator and a 2-channel video DAC with video amplifiers, data manager, luma stage, chroma stage, modulator, and a control interface.

The video encoder also provides the synchronization signals to the display controller: VSYNC, Active Video (AVID), and Field ID (FID).

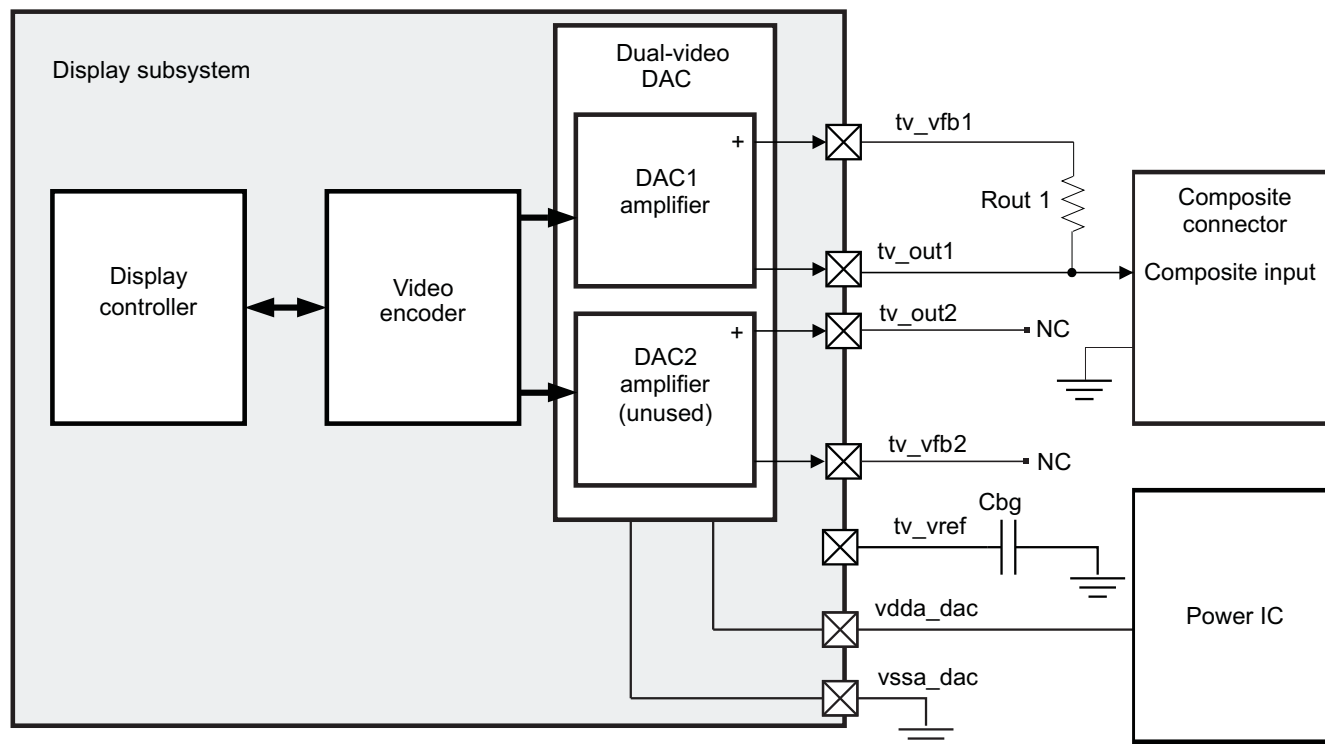

Figure 1-62 is a block diagram of the TV display interface (s-video mode).

**Figure 1-62. TV Display Interface (S-Video Mode)**

dss-035

Figure 1-63 is a block diagram of the TV display interface (composite mode).

**Figure 1-63. TV Display Interface (Composite Mode)**

dss-191

**Note:** In composite video mode, the video DAC2 chroma output must be disabled by setting the DSS.VENC\_OUTPUT\_CONTROL[2] CHROMA\_ENABLE bit to 0.

Table 1-17 describes the interface signals to/from the TV set for the TV display support.

**Table 1-17. TV Display Interface Pins**

Pin Name	Type <sup>(1)</sup>	Description
tv_out1	O	Analog luma or composite video output. An external resistor is connected between this node and tv_vfb1 pin. The nominal value of Rout1 is 1650 Ohm. Note that this is the output node that drives the load (75 Ohm).
tv_out2	O	Analog chroma video output. An external resistor is connected between this node and tv_vfb2 pin. The nominal value of Rout2 is 1650 Ohm. This is the output node that drives the load (75 Ohm).
tv_vfb1	O	Amplifier feedback node. An external resistor is connected between this node and tv_out1. The nominal value of Rout1 is 1650 Ohm.
tv_vfb2	O	Amplifier feedback node. An external resistor is connected between this node and tv_out2. The nominal value of Rout2 is 1650 Ohm.
tv_vref	O	Reference output voltage from internal bandgap. A decoupling capacitor must be connected for optimum performance. tv_vref is generated internally to the OMAP device.
vdda_dac	Power	Analog supply voltage for the dual video DAC
vssa_dac	Power	Analog ground for the dual video DAC

<sup>(1)</sup> O = Output, Power = Power pin

### CAUTION

- tv\_out1 and tv\_out2 are very high-frequency analog signals and must be routed with extreme care. As a result, the path of these signals should be as short as possible, and as isolated as possible from other interfering signals.
- During board design, the onboard traces and parasites must be matched for the two channels. tv\_vfb1 and tv\_vfb2 pins are the most sensitive pins in the TV out system. The onboard parasitic capacitance associated with these two pins should be less than 0.5 pF. Low onboard resistance is required for the traces that connect the Rout1/Rout2 to the tv\_vfb1/tv\_vfb2 and TV OUT pins ( tv\_out1 and tv\_out2). The resistance on those trace affects output impedance matching. Therefore, Rout1 and Rout2 resistors are suggested to be placed as close as possible to the OMAP device pins. The onboard traces lead to the TV OUT pins must have a characteristic impedance of 75-Ohm starting from the closest possible place to the OMAP device pin output. For typical values of Rout1, Rout2, Cout, and Cbg, see the device data manual.
- If the TV output is not used, the analog pins tv\_ref and vdda\_dac must be grounded. The tv\_out1, tv\_out2, tv\_vfb1, and tv\_vfb2 pins can be grounded or left unconnected. To avoid current leakage, the following bits must be set to 0:
  - DSS.DSS\_CONTROL[5] DAC\_POWERDN\_BGZ
  - DSS.VENC\_OUTPUT\_CONTROL[2:0]
  - PRM.CM\_FCLKEN\_DSS[2] EN\_TV
  - CONTROL.CONTROL\_DEVCONF[18] TVOUTBYPASS

Texas Instruments provides a global solution with an OMAP device associated with a TPS65950 power IC. The power pin vdda\_dac is software controlled by the power IC. For more details on the TPS65950 device, contact your TI representative.

#### 1.2.4.1 TV Output and Data Format

The output data to the TV set are the analog composite data from the DAC. The following video standards are supported:

- NTSC-J, M
- PAL-B, D, G, H, I, N
- PAL-M
- PAL-N
- PAL-Nc

#### 1.2.4.2 Digital-to-Analog Converter

The DAC includes the following main features:

- 1.0 V-to-1.3 V digital power supply, 1.8 V analog power supply
- 10-bit resolution
- DNL within 1 least-significant bit (LSB) and INL within 1 LSB
- Sample rate of up to 60 megasamples per second (MSPS)
- Support composite/S-video dc or ac coupled output
- Full-scale voltage output: 0.88 Vpp with a 75-Ohm load
- Internal TV detect feature
- Signal to Noise Ratio (SNR) is 54dB (taking into account the ac coupling)
- Suitable for low-power wireless application; total power: 10 mA (no load in dc coupled mode)
- Power-down mode with less than 2.5-μA standby current
- Differential gain error and differential phase error: 1.5 percent and 1, respectively

---

**Note:** To enhance the TV color display, it is highly recommended to set the DSS.DSS\_CONTROL[4] DAC\_DEMEN bit.

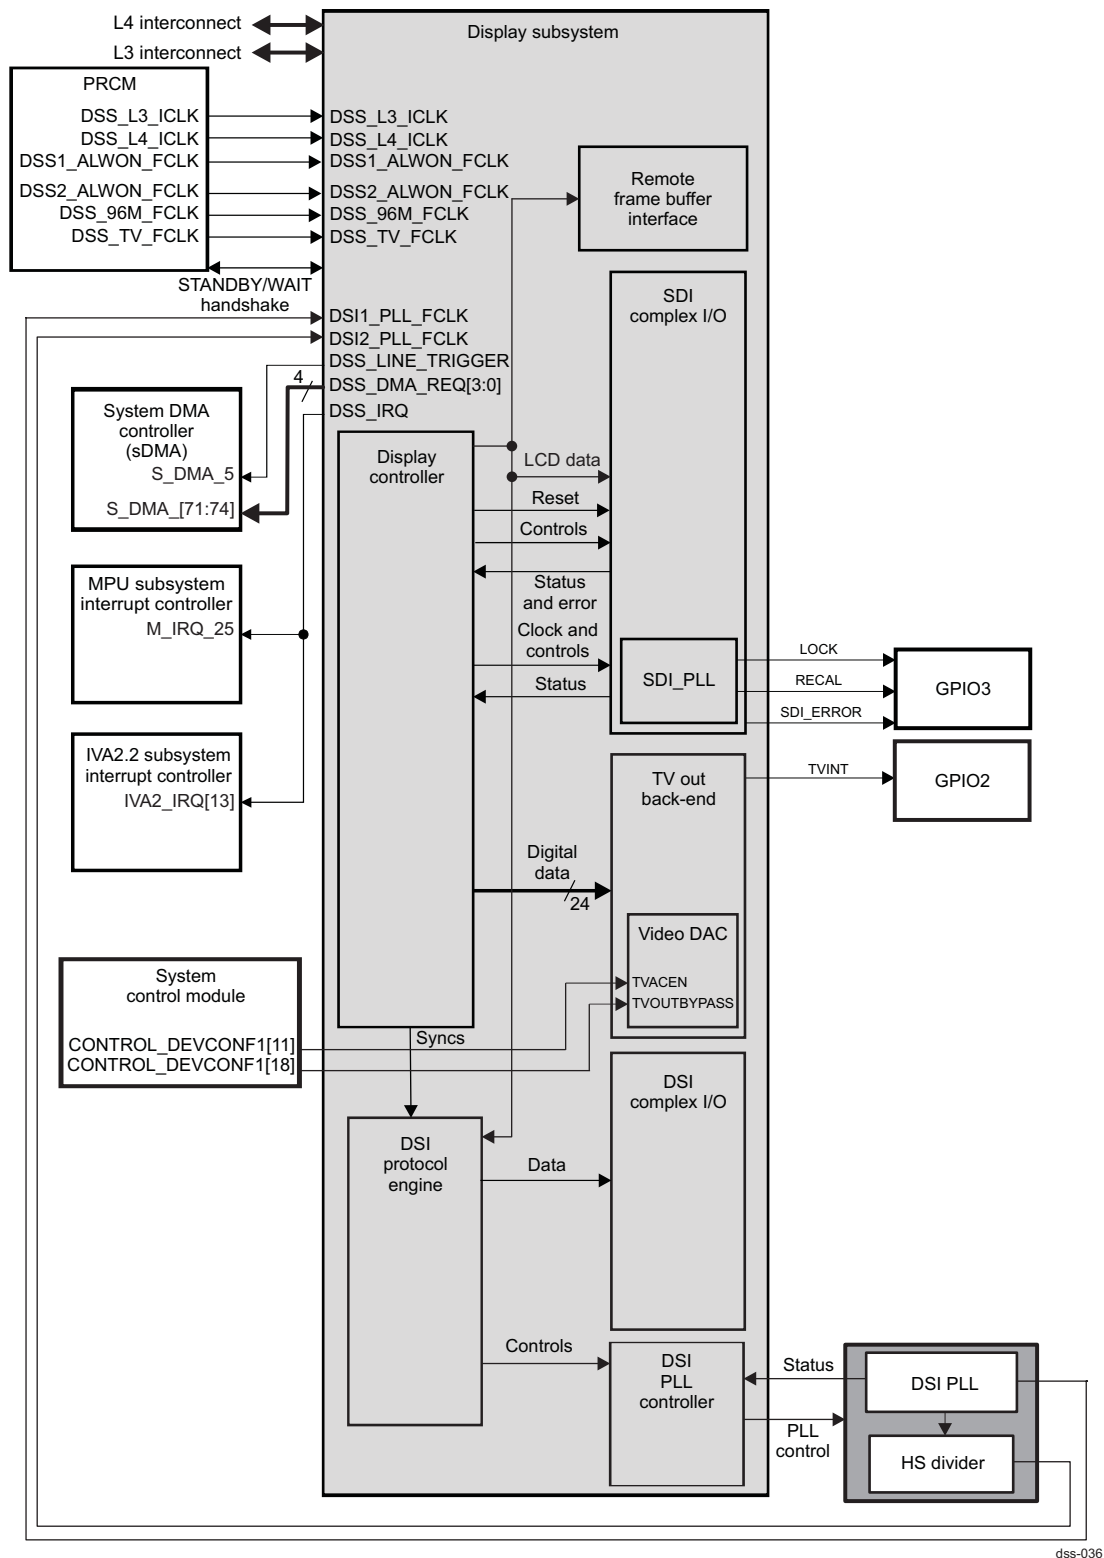

---

### 1.3 Display Subsystem Integration

This section describes the integration of the display subsystem and details clocks, resets, hardware requests, and power modes.

[Figure 1-64](#) shows the integration of the display subsystem in the device.

Figure 1-64. Display Subsystem Integration

dss-036

## 1.3.1 Clocking, Reset, and Power-Management Scheme

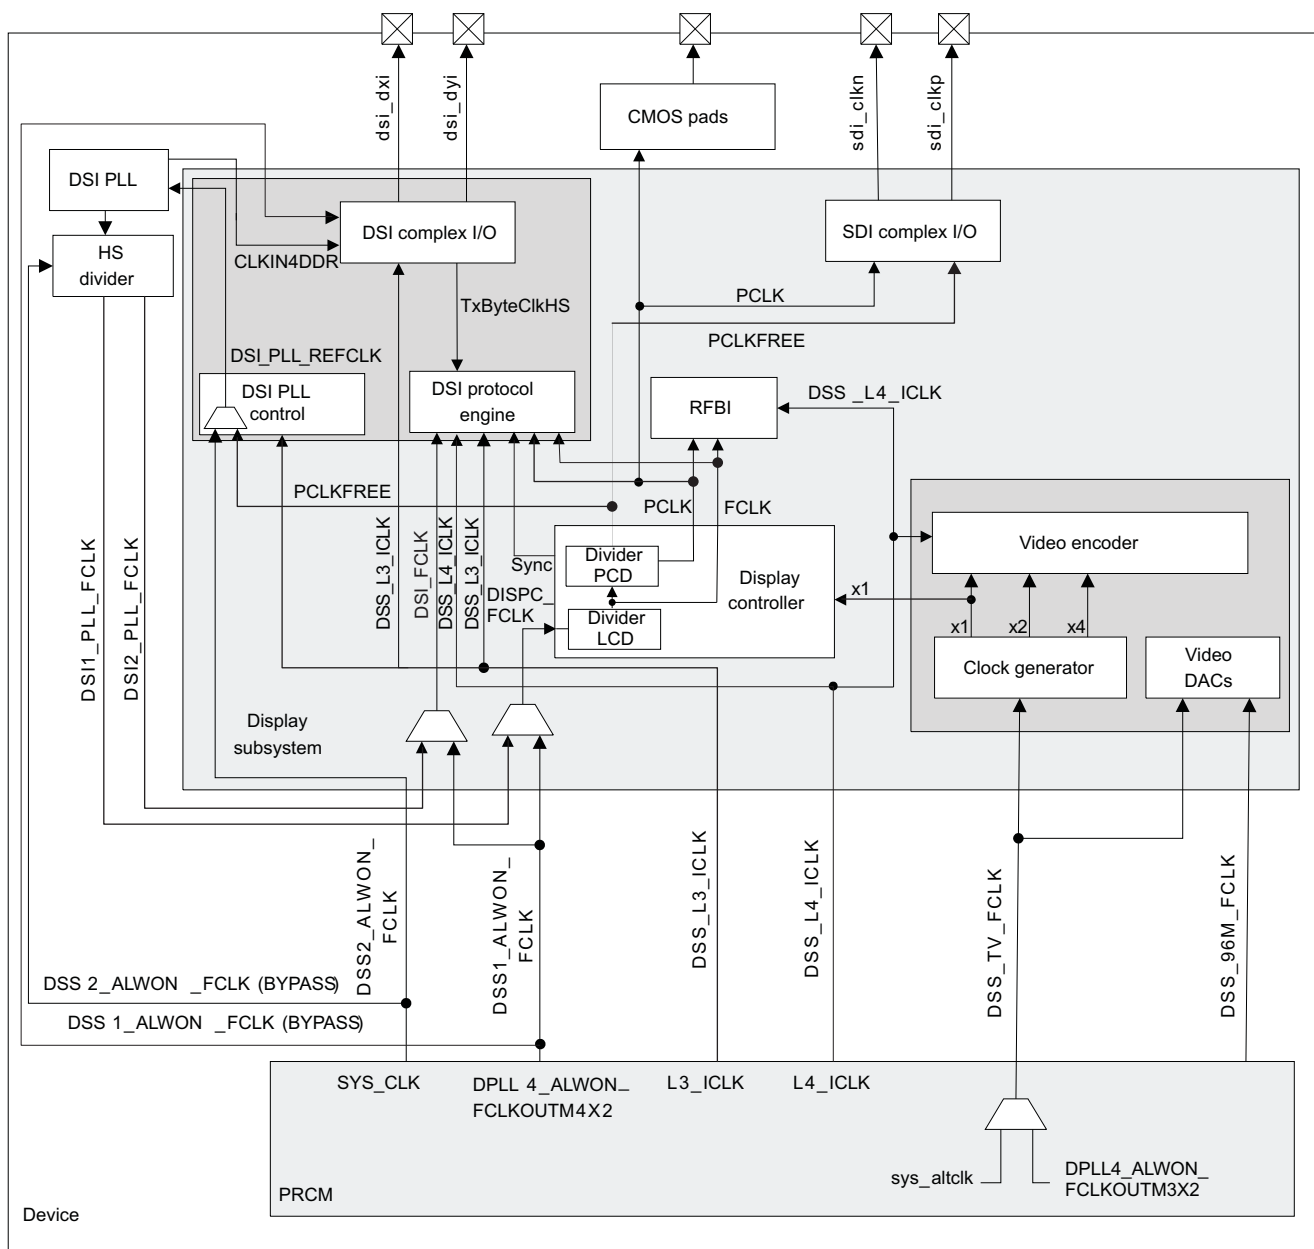

### 1.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides five clock signals to the display subsystem: The L3 interface clock (DSS\_L3\_ICLK) and the L4 interface clock (DSS\_L4\_ICLK) with frequencies respectively equal to the L3 interconnect clock and the L4 interconnect clock; two configurable functional clocks (DSS1\_ALWON\_FCLK and DSS2\_ALWON\_FCLK); and two other functional clocks (DSS\_TV\_FCLK and DSS\_96M\_FCLK).

The DSI PLL provides two functional clock signals to the display subsystem: DSI1\_PLL\_FCLK and DSI2\_PLL\_FCLK.

Figure 1-65 details the clock tree for the display subsystem.

**Figure 1-65. Display Subsystem Clock Tree**

dss-158

**Note:** A synchronization signal is sent by the display controller (DISPC) to the DSI protocol engine. This signal named DISPC\_UPDATE\_SYNC is used to inform the DSI protocol engine that it needs to be unsynchronized with the display controller.

Table 1-18 describes the different clocks with their possible frequency values.

**Table 1-18. Display Subsystem Clocks**

Clock Signal	Attribute	Module	Frequency	Comment
DSS_L3_ICLK	L3 interface clock	DSS	(See the <i>PRCM</i> chapter)	L3 interface clock from PRCM
DSS_L4_ICLK	L4 interface clock	DSS	(See the <i>PRCM</i> chapter)	L4 interface clock from PRCM
DSS1_ALWON_FCLK	Functional clock	DISPC, DSI protocol engine	Up to 173 MHz at nominal voltage	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK)
DSS2_ALWON_FCLK	Functional clock	DSI PLL	12/13/16.8/19.2/26/38.4 MHz	From PRCM: SYS_CLK
DSI1_PLL_FCLK	Functional clock	DISPC, DSI protocol engine	Up to 173 MHz at nominal voltage	From DSI PLL and HS divider
DSI2_PLL_FCLK	Functional clock	DSI protocol engine	Up to 173 MHz at nominal voltage	From DSI PLL and HS divider
DSS_TV_FCLK	Functional clock	DSS, video mode DAC	54 MHz or sys_alt_clk (up to 59 MHz)	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK) or External input clock (See the <i>PRCM</i> chapter)
DSS_96M_FCLK	Functional clock	Video DAC	96 MHz	From PRCM: 96M_FCLK

To enable or disable each functional clock, set the following bit (1: Enable, 0: Disable):

- PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit to enable DSS1\_ALWON\_FCLK
- PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit to enable DSS2\_ALWON\_FCLK
- PRCM.CM\_FCLKEN\_DSS[2] EN\_TV bit to enable DSS\_TV\_FCLK and DSS\_96M\_FCLK

To enable or disable the DSS\_L3\_ICLK and DSS\_L4\_ICLK interface clock, write (1: Enable, 0: Disable) in the PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit.

**Note:** Note that it is not possible to gate/stop L3 clock and keep L4 clock running.

- L3 and L4 interface clock

The DSS\_L3\_ICLK clock is used only by the display controller interface to fetch the pixel data. The DSS\_L4\_ICLK is used to access the L4 interconnect for configuring all the display subsystem registers.

**Note:** A clock generated internally from the L3 interface clock allows the submodules to be configured and is the functional clock for the RFBI. The SDI module is configured through the display subsystem register, as well as all display subsystem registers.

- Display controller functional clocks

The display controller can use either the DSS1\_ALWON\_FCLK or the DSI1\_PLL\_FCLK functional clock.

To select the DSS1\_ALWON\_FCLK functional clock (the default clock selected after reset), write 0 in the DSS.DSS\_CONTROL[0] DISPC\_CLK\_SWITCH bit; to select the DSI1\_PLL\_FCLK functional clock, write 1 in the DSS.DSS\_CONTROL[0] DISPC\_CLK\_SWITCH bit.

---

**Note:** The DSS1\_ALWON\_FCLK and DSI1\_PLL\_FCLK functional clocks must be active (the PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 and DSI PLL programmed correctly) to switch from one functional clock to another. The new functional clock is effective when the next vertical blanking interval occurs. This is true only if the DSS.DISPC\_CONTROL[5] GOLCD bit is set to 1.

---

Depending on the DPLL4 input clock frequency, the DSS1\_ALWON\_FCLK can be adjusted by setting the PRCM.CM\_CLKSEL\_DSS[4:0] CLKSEL\_DSS1 field.

- DSI PLL functional clock (DSI\_PLL\_REFCLK)  
The DSI PLL controller module can use either the DSS2\_ALWON\_FCLK (from PRCM) or PCLKFREE (from DISPC) functional clock. To select the DSS2\_ALWON\_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSI\_PLL\_CONFIGURATION2[11] DSI\_PLL\_CLKSEL bit; to select the PCLKFREE functional clock, write 1 in the DSS.DSI\_PLL\_CONFIGURATION2[11] DSI\_PLL\_CLKSEL bit.
- DSI protocol engine functional clocks (DSI\_FCLK)  
The DSI protocol engine can use either the DSS1\_ALWON\_FCLK (from PRCM) or DSI2\_PLL\_FCLK (from DSI PLL) functional clock. To select the DSS1\_ALWON\_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSS\_CONTROL[1] DSI\_CLK\_SWITCH bit; to select the DSI2\_PLL\_FCLK functional clock, write 1 in the DSS.DSS\_CONTROL[1] DSI\_CLK\_SWITCH bit.

---

**Note:** It is possible to switch between these two clocks even when both of them are not active.

---

- There are five clock domains in the DSI module:
  - Byte clock domain:  
TxByteClkHS is generated from the bit clock and converted into byte clock. The maximum frequency is 100 MHz (all OPPs). It is generated by the DSI complex I/O.
  - Functional Clock domain  
The DSI\_FCLK is the functional clock for the DSI Protocol engine module. The maximum frequency is 173 MHz (nominal voltage) and 124 MHz (low voltage). It should be always higher than Byte clock, L4 interconnect clock and video port clock. The software should correctly configure the clocks.
  - L4 interface clock domain  
The DSS\_L4\_ICLK is used in the L4 interconnect port domain. The maximum frequency is 166 MHz at nominal voltage and 83 MHz at low voltage.
  - The video port domain  
The pixel clock (PCLK) on the video port is used by the video port domain to capture the pixels from the display controller. The maximum frequency of VP\_CLK used as the functional clock for the video port domain is 173 MHz at nominal voltage and 96 MHz at low voltage.
  - Serial Configuration Port (SCP) and Power Control (PWR) interfaces  
The DSS\_L4\_ICLK is the functional clock.

---

**Notes:**

- There is no clock domain for RxClkEsc since it is used as an enable and not as a clock by the DSI protocol engine module
  - The clock domains are asynchronous (except for L4 interconnect port and SCP/PWR since them both use DSS\_L4\_ICLK). The clocks used for the L4 interconnect port and SCP/PWR interface should be balanced.
  - If video mode is used, the display controller functional clock must be generated using a clock from the DSI PLL.
- 

- Video encoder functional clock  
The DSS\_TV\_FCLK is divided into three balanced clocks, depending on the clock mode selected (see [Table 1-19](#)).

**Table 1-19. Possible Digital Clock Division for the Video Encoder**

Clock Output	Clock Mode	
	Clock mode 0	Clock mode 1
Video encoder clock 4x	DSS_TV_FCLK	DSS_TV_FCLK or 0 (gated)
Video encoder clock 2x	DSS_TV_FCLK/2	DSS_TV_FCLK
Video encoder clock 1x	DSS_TV_FCLK/4	DSS_TV_FCLK/2

**Note:** Clock mode 1 can be used for power saving purposes or if a 27-MHz external clock is provided to the video encoder.

The DSS\_TV\_FCLK can be adjusted depending on the DPLL4 input clock frequency by setting the PRCM.CM\_CLKSEL\_DSS[12:8] CLKSEL\_TV field. If the DPLL4 is selected, the DSS\_TV\_FCLK is provided by the DPLL4\_ALWON\_FCLKOUTM3X2 clock.

**Note:** If the DSS\_TV\_FCLK is not provided by DPLL4 but rather by the sys\_alt\_clk pin, an external clock generator must be connected to this pin. In this case, a 54-MHz clock is needed for PAL or NTSC 601, a 49.09-MHz clock is needed for NTSC square pixel and a 59-MHz clock is needed for PAL square pixel.

- **Dual video DAC clocks**  
The dual video DAC uses two distinct clocks: The DSS\_TV\_FCLK and the DSS\_96M\_FCLK. The video data are latched on the positive edge of the DSS\_TV\_FCLK clock. On the other hand, the video DAC uses DSS\_96M\_FCLK fixed-frequency clock internally as the clock input for the switch capacitor resistor.
- **SDI functional clock**  
The display controller provides the functional clocks PCLK (pixel clock) and PCLKFREE (pixel clock free-running) of the SDI module, which is derived from the functional clock of the display controller. The functional clock of the SDI module drives the phase-locked loop SDI\_PLL that multiplies and divides the PCLK frequency by two programmable factors for the serial connection. This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

**Note:** When using the SDI, configure the PCLK in the free-running mode by setting the DSS.DISPC\_CONTROL[27] PCLKFREEENABLE bit to 1.

## 1.3.1.2 Resets

### 1.3.1.2.1 Hardware ResetSDI Clock Source/Frequency Change Sequence Part A

The display subsystem receives its reset signal DSS\_RST (the reset signal of the display subsystem [DSS] power domain) from the PRCM module.

### 1.3.1.2.2 Software Reset

The display subsystem can receive a software reset propagated through all of the submodules and used to initialize the display subsystem. To apply the reset, write the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit (1: Reset; 0: Normal). The DSS.DSS\_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1.

**Note:** The display controller, the DSI protocol engine, and the RFBI modules also have their own software reset functionality. To access this reset, access the DSS.DISPC\_SYSCONFIG[1] SOFTRESET bit for the display controller, the DSS.DSI\_SYSCONFIG[1] SOFTRESET bit for the DSI protocol engine, and the DSS.RFBI\_SYSCONFIG[1] SOFTRESET bit for the RFBI module.

To properly reset these modules, 0x2 is the only valid value to write in these registers.

### CAUTION

All the interface and functional clocks, even for the TV output, must be provided to the display subsystem to update the RESETDONE status bit correctly.

### 1.3.1.3 Power Domain

The display subsystem modules are on the Display subsystem (DSS) power domain and on the VDD2 voltage domain, except the dual video DACs, which are on the analog VDDADAC voltage domain.

### 1.3.1.4 Power Management

#### 1.3.1.4.1 Clock Activity Mode

The display controller clocks can be configured as one of the following clock activity modes:

- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x1: The functional clocks can be can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x2: The interface clocks can be can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSI protocol engine clocks can be configured in one of the following clock activity modes:

- DSS.DSI\_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DSI\_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DSI\_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x2: The interface clocks can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSS power domain clock activity status is logged in the PRCM.CM\_CLKSTST\_DSS[0] CLKACTIVITY\_DSS status bit. When set to 0, there is no domain clock activity. When set to 1, the DSS power domain clock is active.

**Note:** The display subsystem interface clock can be dependent on the DSS power domain state. This is configured with PRCM.CM\_AUTOIDLE\_DSS[0] AUTO\_DSS bit:

- When the AUTO\_DSS bit is set to 0 (reset value): The display subsystem interface clock is not related to the DSS power domain state transition.
- When the AUTO\_DSS bit is set to 1: The display subsystem interface clock is automatically enabled or disabled along with the DSS power domain state transition.

### 1.3.1.4.2 Autoidle Mode

The RFBI, display controller, DSI protocol engine, and L4 interfaces can internally gate their clocks to decrease power consumption, if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DSI\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the DSI protocol engine
- DSS.DISPC\_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled; 0: Functional clocks gated disabled) for the display controller

---

**Note:** All the bits listed above (except FUNCGATED bit) are set to 1 by default. It is highly recommended to set all the bits to 1 to save power.

---

### 1.3.1.4.3 Idle Mode

The display controller, DSI protocol engine, and RFBI can be configured into one of the following acknowledgment modes:

- Force-idle mode: The module immediately enters the idle state on receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state. Set the DSS.DISPC\_SYSCONFIG[4:3] SIDLEMODE field to 0x0 (reset value) for display controller, set the DSS.DSI\_SYSCONFIG[4:3] SIDLEMODE field to 0x0 (reset value) for DSI protocol engine, and, finally, the DSS.RFBI\_SYSCONFIG[4:3] SIDLEMODE field to 0x0 (reset value) for RFBI.
- No-idle mode: The module never enters the idle state. Set the DSS.DISPC\_SYSCONFIG[4:3] SIDLEMODE field to 0x1 for display controller, set the DSS.DSI\_SYSCONFIG[4:3] SIDLEMODE field to 0x1 for DSI protocol engine, and, finally, the DSS.RFBI\_SYSCONFIG[4:3] SIDLEMODE field to 0x1 for RFBI.
- Smart-idle mode:
  - Display controller: After receiving a low-power-mode request from the PRCM module, the display controller module enters the idle state when all the following conditions are satisfied:
    - All asserted output interrupts are acknowledged (no interrupt pending)
    - The display controller does not use anymore the L4 interface clock (DSS\_L4\_ICLK)
  - DSI Protocol engine: After receiving a low-power-mode request from the PRCM module, the DSI protocol engine enters the idle state when all the following conditions are satisfied:
    - All asserted output interrupts are acknowledged (no interrupt pending)
    - The DSI protocol engine does not use anymore the L4 interface clock (DSS\_L4\_ICLK)
    - The SCP and PWR transactions are completed
    - No data in the TX FIFO (data waiting in the FIFO to be sent to the peripheral)

To configure the display subsystem in smart-idle mode, set the DSS.DISPC\_SYSCONFIG[4:3] SIDLEMODE field to 0x2 for display controller, set the DSS.DSI\_SYSCONFIG[4:3] SIDLEMODE field to 0x2 for DSI protocol engine, and, finally, the DSS.RFBI\_SYSCONFIG[4:3] SIDLEMODE field to 0x2 for RFBI.

Once the idle handshake protocol is over:

- The DSS L4 interface clock (DSS\_L4\_ICLK) can be shutdown at any time.
- Any transaction on the L4 configuration port is ignored.

### 1.3.1.4.4 SDI Idle Mode

To save power consumption, the PLL (SDI\_PLL) of the SDI module can be configured in one of the operation modes shown in [Table 1-20](#) when not locked.

**Table 1-20. SDI PLL Operation Modes**

SDI_PLL Operation Mode	Stop mode Low power <sup>(1)</sup>	Stop mode Low power <sup>(1)</sup>	Idle bypass Low power	Idle bypass Fast relock	Limp
	Output clock stopped Lowest power standby	Output clock stopped Fastest start-up time	Output clock at PCLK rate Lowest power standby	Output clock at PCLK rate Fastest start-up time	Output at full speed
DSS.DSS_PLL_CONTROL[0] SDI_PLL_IDLE	0	0	1	1	1 or PCLK stops
DSS.DSS_PLL_CONTROL[20] SDI_PLL_LOWCURRSTBY	1	0	1	0	X
DSS.DSS_PLL_CONTROL[17] SDI_PLL_STOPMODE	1	1	1	1	0

<sup>(1)</sup> Recommended

### 1.3.1.4.5 Wake-Up Mode

The Display Controller (DISPC) supports the wake-up protocol. The mode is selected by programming the appropriate value in the DSS.DISPC\_SYSCONFIG[2] ENWAKEUP bit. The wake-up signal is asserted when the DISPC is in idle mode and when anyone of the following events occur:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- The current pixel is the last pixel displayed on the LCD panel if it is not the last frame.
- The current pixel is the last pixel displayed on the digital panel if it is not the last frame.

If software users set the DSS.DISPC\_CONFIG[17] FIFOFILLING bit, when one of the active pipe reaches the low threshold and should refill the FIFO for the current frame, the other pipes also refill their own FIFOs, even if the low threshold has not been reached. This is used to improve the probability of increasing the time when there is no access to the L3 interconnect (MStandby asserted, affects power savings).

Once the wake-up signal is asserted, the WAKEUP interrupt request is generated. The wake-up signal is deasserted when the idle request is no longer activated.

### 1.3.1.4.6 Standby Mode

As part of the system-wide power-management scheme, the display controller can enter standby mode. To configure the display controller, write the DSS.DISPC\_SYSCONFIG[13:12] MIDDLEMODE field (00: Forced standby; 01: No standby; 10: Smart standby) in one of the following standby modes:

- Forced standby mode (default mode): The module enters standby mode when the module is disabled.
- No standby mode: The module never enters standby mode.
- Smart standby mode: The module enters standby state when the DISPC module is disabled or when all the three following events occur:
  - Graphics pipe is disabled or graphics pipe is enabled but data fetch completed for graphics window, or graphics pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
  - Video1 pipe is disabled or video1 pipe is enabled but data fetch completed for video1 window, or video1 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
  - Video2 pipe is disabled or video2 pipe is enabled but data fetch completed for video2 window, or video2 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater

than the high threshold programmed value.

When in standby mode, the display controller does not generate transactions on the L3 master port. Standby is active when the PRCM module confirms this mode.

The display subsystem standby mode activity can be monitored with the PRCM.CM\_IDLEST\_DSS[0] ST\_DSS status register. When this register is read to 0, the display subsystem is accessible and the interface clock running; when it is read to 1, the display subsystem is in standby mode.

#### 1.3.1.4.6.1 Conditions to Exit Standby Mode

The following conditions allow the subsystem to exit standby mode:

- Forced standby mode: Standby mode is exited when the display controller is enabled.
- Smart standby mode: Standby mode is exited when any one of the following events occurs:
  - Graphics pipe is enabled and data fetch is not completed for graphics window, and number of data bytes in FIFO is less than the low threshold programmed value.
  - Video1 pipe is enabled and data fetch is not completed for video1 window, and number of data bytes in FIFO is less than the low threshold programmed value.
  - Video2 pipe is enabled and data fetch is not completed for video2 window, and number of data bytes in FIFO is less than the low threshold programmed value.

#### 1.3.1.4.6.2 Standby Transition Dependency

The sleep transition of the DSS power domain can be dependent or not with respect to MPU domain. This is configured by PRCM.CM\_SLEEPDEP\_DSS[1] EN\_MPU bit:

- When the EN\_MPU bit is set to 0 (reset value): The DSS power domain sleep dependency with the MPU power domain is disabled. The DSS power domain will not enter idle unless the MPU power has previously entered idle.
- When the EN\_MPU bit is set to 1: The DSS power domain sleep dependency with the MPU power domain is enabled. The DSS power domain will enter idle regardless of the power domain state of the MPU.

The sleep transition of the DSS power domain may, or may not depend on the IVA2.2 domain, depending on the configuration of the PRCM.CM\_SLEEPDEP\_DSS[2] EN\_IVA2 bit:

- When the EN\_IVA2 bit is set to 0 (reset value): The DSS power domain sleep dependency on the IVA2.2 power domain is disabled.
- When the EN\_IVA2 bit is set to 1: The DSS power domain sleep dependency on the IVA2.2 power domain is enabled.

#### 1.3.1.4.6.3 Standby Procedure Description

When the display subsystem initiates a standby procedure, it also initiates an standby/wait handshake protocol with the PRCM module that lets the PRCM cut the display subsystem clocks. Depending on the PRCM setting, two modes are available:

- Manual mode
  - DSS1\_ALWON\_FCLK is shut down when the PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit is set to 0 and the display subsystem is in standby mode.
  - DSS2\_ALWON\_FCLK is shut down when the PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit is set to 0 and the display subsystem is in standby mode.
  - DSS\_L3\_ICLK and DSS\_L4\_ICLK are controlled together. They are shut down when the PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit is set to 0 and the display subsystem is in standby mode.

#### CAUTION

Do not stop DSS1\_ALWON\_FCLK, or DSS2\_ALWON\_FCLK clock (if used) if the display subsystem is not disabled.

### CAUTION

DSS\_TV\_FCLK does not depend on the display subsystem standby state. Ensure correct clock management for DSS\_TV\_FCLK.

The clocks are reactivated when the related bits are set to 1 and the display subsystem exits from standby. For more information, see the *Power, Reset, and Clock Management* chapter.

- Hardware- or software-supervised mode

The DSS-power state-transition between active and inactive states can be either hardware or software supervised. This is programmed with the PRCM.CM\_CLKSTCTRL\_DSS[1:0] CLKTRCTRL\_DSS field:

- When the CLKTRCTRL\_DSS field is set to 0x0 (reset value), the automatic transition is disabled
- When the CLKTRCTRL\_DSS field is set to 0x1, the software-supervised sleep transition is started on the DSS power domain.
- When the CLKTRCTRL\_DSS field is set to 0x2, the software-supervised wake-up transition is started on the DSS power domain.
- When the CLKTRCTRL\_DSS field is set to 0x3, the automatic transition is enabled. Any transition on the DSS power domain is supervised by the hardware.

#### 1.3.1.4.6.4 Display Subsystem Standby Mode, Power-Saving Use Cases

- Setup
  - Set the display subsystem in smart standby mode.
  - Manually enable DSS\_L3\_ICLK and DSS\_L4\_ICLK.
  - Manually enable DSS1\_ALWON\_FCLK or DSS2\_ALWON\_FCLK.
  - Manually enable DSS\_TV\_FCLK if the video encoder is used.
  - Set the PRCM.CM\_CLKSTCTRL\_DSS[1:0] CLKTRCTRL\_DSS field to 0x3 (autocontrol mode supervised by hardware).
- Shut down the display subsystem.
  - Disable the display subsystem.
  - Manually disable DSS1\_ALWON\_FCLK, DSS2\_ALWON\_FCLK, DSS\_TV\_FCLK, DSS\_L3\_ICLK, and DSS\_L4\_ICLK.

For more details on low-power programming settings, see [Section 1.6.2](#).

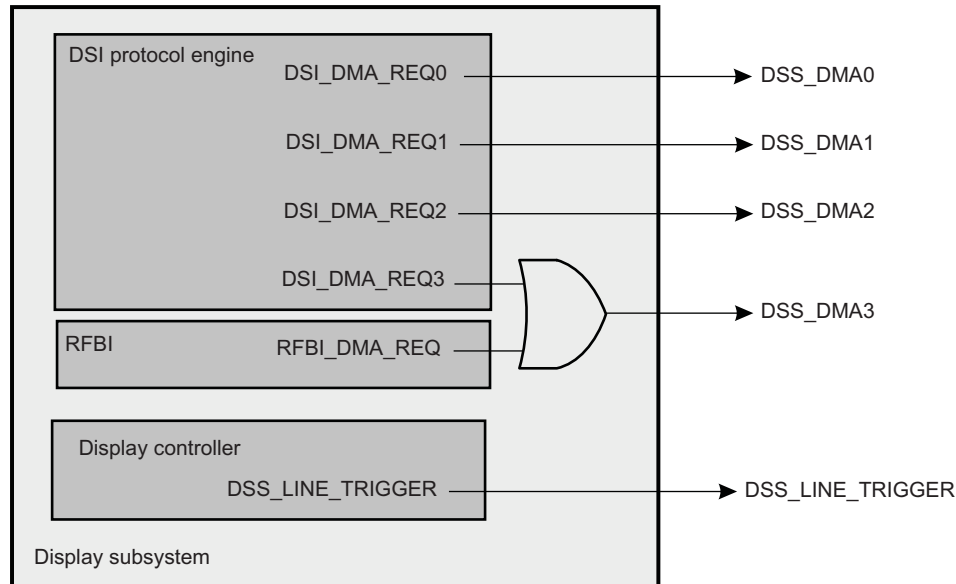

## 1.3.2 Hardware Requests

### 1.3.2.1 DMA Requests

The display controller, the DSI protocol engine, and the RFBI generate some DMA requests to the sDMA. [Figure 1-66](#) details the DMA tree.

**Figure 1-66. Display Subsystem DMA Tree**

dss-159

**Table 1-21. DSS DMA Requests Description**

DMA Request Name	DSS Module	Mapping	Description
DSS_LINE_TRIGGER	DISPC	S_DMA_5	See <a href="#">Section 1.3.2.1.1</a>
DSI_DMA_REQ0	DSI protocol engine	S_DMA_71	See <a href="#">Section 1.3.2.1.2</a>
DSI_DMA_REQ1	DSI protocol engine	S_DMA_72	See <a href="#">Section 1.3.2.1.2</a>
DSI_DMA_REQ2	DSI protocol engine	S_DMA_73	See <a href="#">Section 1.3.2.1.2</a>
DSI_DMA_REQ3	DSI protocol engine	S_DMA_74	See <a href="#">Section 1.3.2.1.2</a>
RFBI_DMA_REQ	RFBI	S_DMA_74	See <a href="#">Section 1.3.2.1.3</a>

**Note:** The DMA requests from the RFBI module (RFBI\_DMA\_REQ) and the DSI protocol engine (DSI\_DMA\_REQ3) are merged on line DSS\_DMA3. The software should only use DSS\_DMA3 on one module at a time (RFBI or DSI protocol engine).

#### 1.3.2.1.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS\_LINE\_TRIGGER) is connected to the sDMA by the sDMA controller (S\_DMA\_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This request is related to an interrupt event described in [Section 1.3.2.2, Interrupt Requests](#). This allows the sDMA channel to be synchronized with the Display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS\_LINE\_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC\_LINE\_NUMBER[10:0] LINENUMBER field.

### 1.3.2.1.2 DSI Protocol Engine DMA Request

The DSI DMA requests are used to allow automatic transfer by the sDMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same virtual channel are supported.

### 1.3.2.1.3 RFBI DMA Request

The RFBI\_DMA\_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

## 1.3.2.2 Interrupt Requests

The DSI protocol engine, the DSI complex I/O (DSI\_IRQ), and the display controller (DISPC\_IRQ) generate one interrupt request each. The DSI\_IRQ and DISPC\_IRQ lines are merged together in a single interrupt line.

One interrupt line (DSS\_IRQ) is connected to two interrupt controllers:

- MPU interrupt controller (M\_IRQ\_25 input line)
- IVA interrupt handler (IVA2\_IRQ[13] input line)

Figure 1-67 shows the interrupt tree for the DSI protocol engine and DSI complex I/O in detail.

**Figure 1-67. DSI Interrupt Tree**

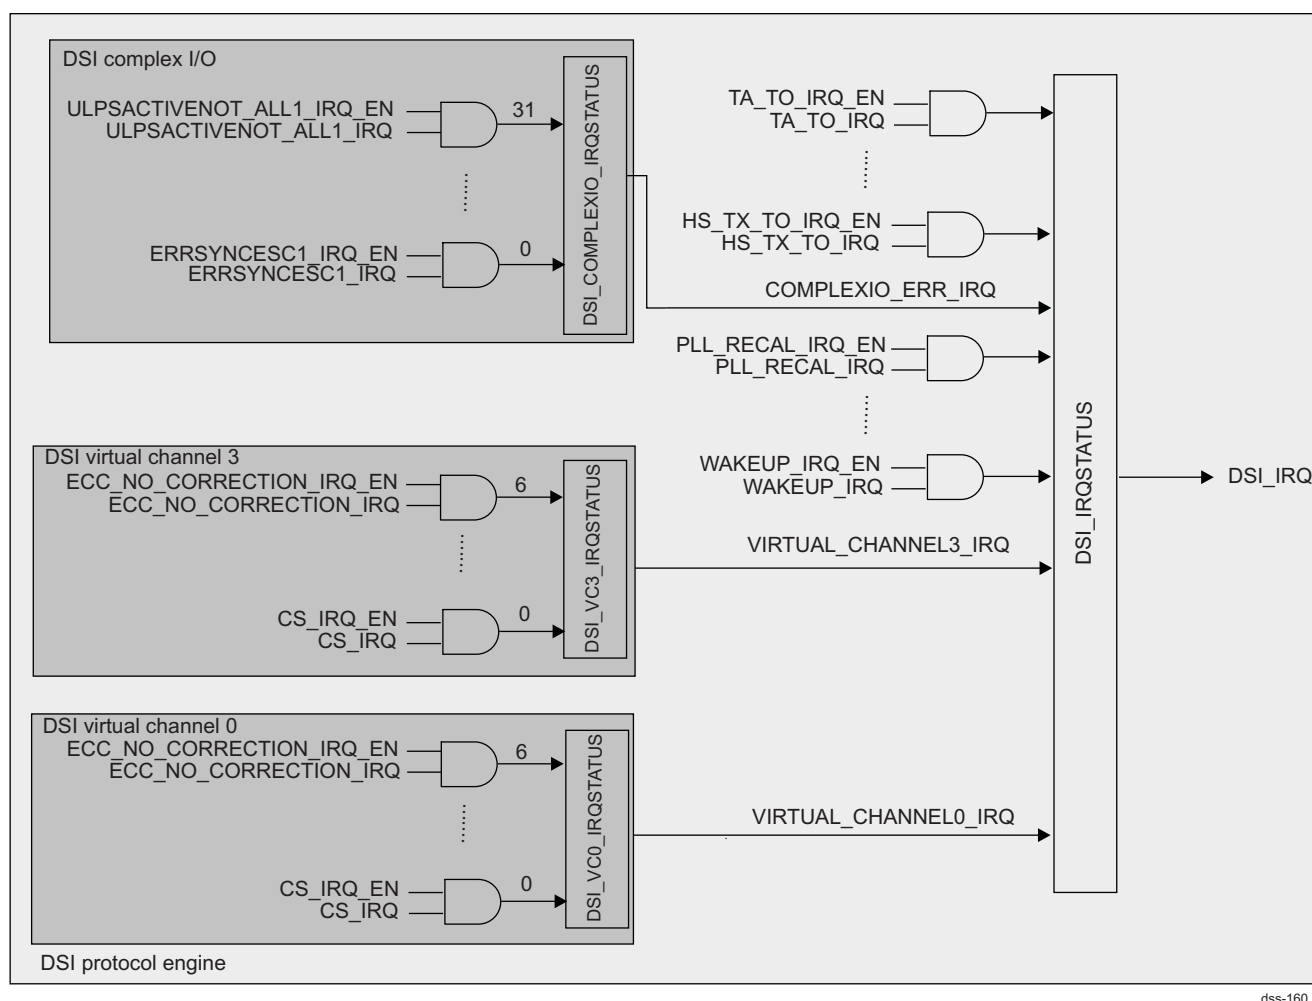

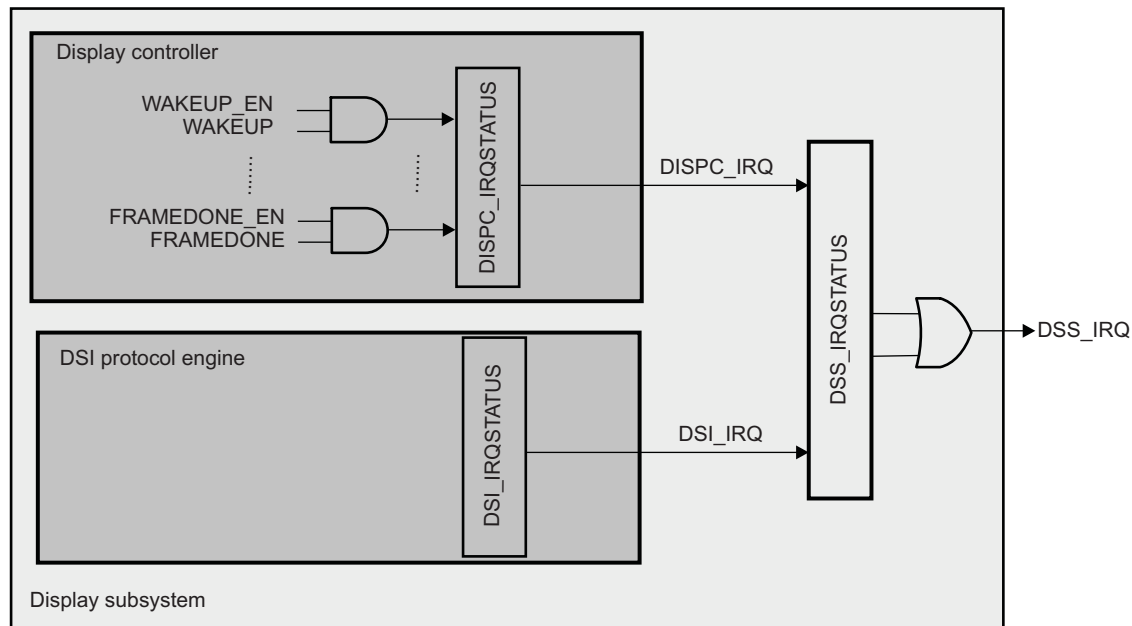

Figure 1-68 details the interrupt tree for the DISPC and the display subsystem.

**Figure 1-68. DISPC and DSS Interrupts Tree**

dss-161

#### 1.3.2.2.1 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DSS.DISPC\_IRQENABLE register.

To check when a particular interrupt event occurs and to reset a particular event, the DSS.DISPC\_IRQSTATUS register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See [Section 1.7, Display Subsystem Registers](#), for more information on checking and clearing interrupt events.

[Table 1-22](#) lists the display subsystem interrupt events.

**Table 1-22. Display Subsystem Interrupts**

Interrupt Name	Description
FRAMEDONE	Active frame is complete and LCD output is disabled.
VSYNC	VSYNC interrupt occurred at the end of the frame.
EVSYNC_EVEN <sup>(1)</sup>	EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.)
EVSYNC_ODD <sup>(1)</sup>	EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.)
ACBIASCOUNTSTATUS	The ac-bias transition counter decremented to 0.
PROGRAMMEDLINENUMBER	The LCD reached the user-programmed line number.
GFXFIFOUNDERFLOW	The input graphics FIFO goes underflow.
GFXENDWINDOW	The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen.
PALETTEGAMMALOADING	The palette/gamma table is loaded.
OCPPERROR	L3 interconnect sent SResp = ERR.
VID1FIFOUNDERFLOW	The input video1 FIFO goes underflow.

<sup>(1)</sup> EVYNC interrupts (EVSYNC\_EVEN and EVSYNC\_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

**Table 1-22. Display Subsystem Interrupts (continued)**

Interrupt Name	Description
VID1ENDWINDOW	The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen.
VID2FIFOUNDERFLOW	The input video2 FIFO goes underflow.
VID2ENDWINDOW	The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen.
SYNCLOST	Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOSTDIGITAL	Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly.
WAKEUP	Occurs when the wakeup signal is asserted

**Note:** To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC\_CONTROL[0] LCDENABLE (LCD: SYNCLOST interrupt) or DSS.DISPC\_CONTROL[1] DIGITALENABLE (TV: SYNCLOSTDIGITAL interrupt) bits.  
Check the interrupts.  
LCD: Verify that a FRAMEDONE interrupt occurs.  
TV : Verify that EVSYNC\_EVEN or EVSYNC\_ODD interrupts occur.
2. Set the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
3. Set the display subsystem registers again.

**Note:** The SYNCLOSTDIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), should not be considered.

After the first VSYNC pulse signal, the SYNCLOSTDIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC\_IRQSTATUS[15] SYNCLOSTDIGITAL bit; then the SYNCLOSTDIGITAL interrupt can be enabled by setting the DSS.DISPC\_IRQENABLE[15] SYNCLOSTDIGITAL bit.

## 1.4 Display Subsystem Functional Description

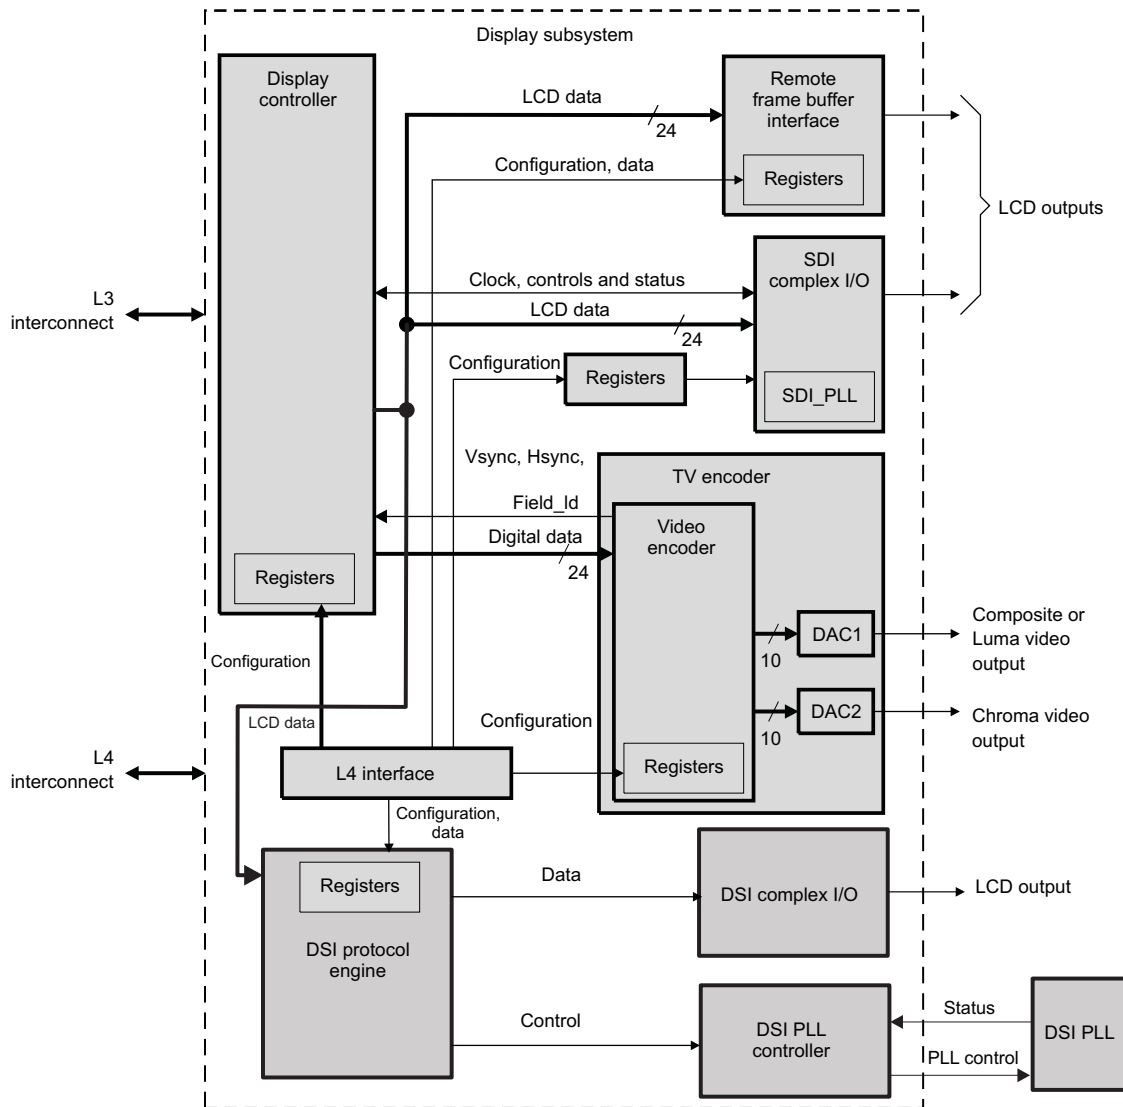

This section describes the functionalities of the LCD and TV display supports by describing the following modules: Display controller, DSI protocol engine, DSI PLL controller, DSI complex I/O, RFBI, SDI, and video encoder.

The functionalities of the display controller are common to both LCD and TV data paths; the RFBI and SDI functionalities are LCD-specific; and the video encoder functionalities are specific to the TV set.

### 1.4.1 Block Diagram

Figure 1-69 is a schematic of the display subsystem.

Figure 1-69. Display Subsystem Full Schematic

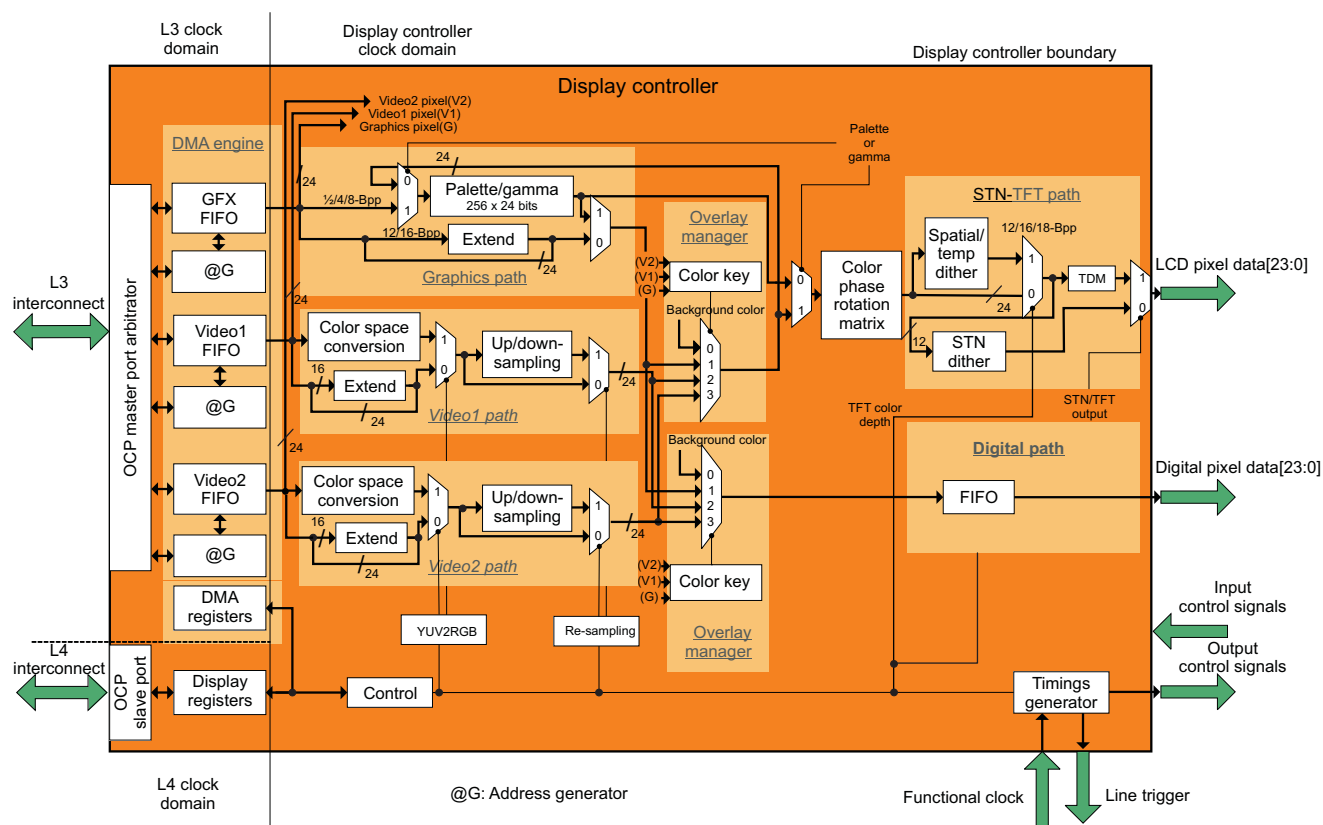

dss-037

## 1.4.2 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see Figure 1-70).

Figure 1-70. Display Controller Architecture Overview

dss-038

Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

## 1.4.2.1 Display Modes

### 1.4.2.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

### 1.4.2.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

## 1.4.2.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

### 1.4.2.2.1 Graphics Memory Format

The supported formats for the graphics layer are color lookup table (CLUT) bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (Little Endian)

- BITMAP 1-BPP data memory organization (CLUT) (Little Endian + Nibble Mode)

- BITMAP 1-BPP data memory organization (CLUT) (Big Endian)

- BITMAP 1-BPP data memory organization (CLUT) (Big Endian + Nibble Mode)

- BITMAP 2-BPP data memory organization (CLUT) (Little Endian)

- BITMAP 2-BPP data memory organization (CLUT) (Little Endian + Nibble Mode)

- BITMAP 2-BPP data memory organization (CLUT) (Big Endian)

- BITMAP 2-BPP data memory organization (CLUT) (Big Endian + Nibble Mode)

- BITMAP 4-BPP data memory organization (CLUT) (Little Endian)

- BITMAP 4-BPP data memory organization (CLUT) (Little Endian + Nibble Mode)

- BITMAP 4-BPP data memory organization (CLUT) (Big Endian)

- BITMAP 4-BPP data memory organization (CLUT) (Big Endian + Nibble Mode)

- BITMAP 8-BPP data memory organization (CLUT) (Little Endian)

#### 1.4.2.2.2 Color Look-Up Table/Gamma Table

The graphics path supports the palette/gamma table. [Figure 1-71](#) shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

**Figure 1-71. Palette/Gamma Correction Architecture**

dss-054

#### 1.4.2.2.2.1 Color Look-Up Table

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In the color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). In the monochrome mode, only one 8-bit value is present.

After passing through the palette, 256 grayscales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 grayscales and 3375 colors.

- Passive matrix technology  
The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology  
The palette is bypassed in 12, 16, and 24 BPP, allowing up to  $2^{24} = 16,777,216$  colors to be displayed.

#### 1.4.2.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component.

#### 1.4.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

dss-T055

- If replication logic is ON:

dss-T056

- If replication logic is OFF:

dss-T057

#### 1.4.2.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV422 pixels.

##### 1.4.2.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

### 1.4.2.3.2 Color Space Conversion

The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. [Figure 1-72](#) and [Figure 1-73](#) detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

**Figure 1-72. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)**

**Figure 1-73. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)**

The interpolation of the missing chrominance component is given by the equation in [Figure 1-74](#).

**Figure 1-74. Interpolation of the Missing Chrominance Component**

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. The user sets the coefficients according to the standard used to encode the pixel data in YCbCr color space.

In case of resampling, the YUV422 format is converted into YUV444. The YUV422-to-YUV444 processing is bypassed in the color space conversion unit.

If the active range for the luminance samples (Y) is [16235] and [16240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 1-75](#) gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

**Figure 1-75. YCbCr to RGB Registers (VIDFULLRANGE=0)**

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 1-76](#) gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

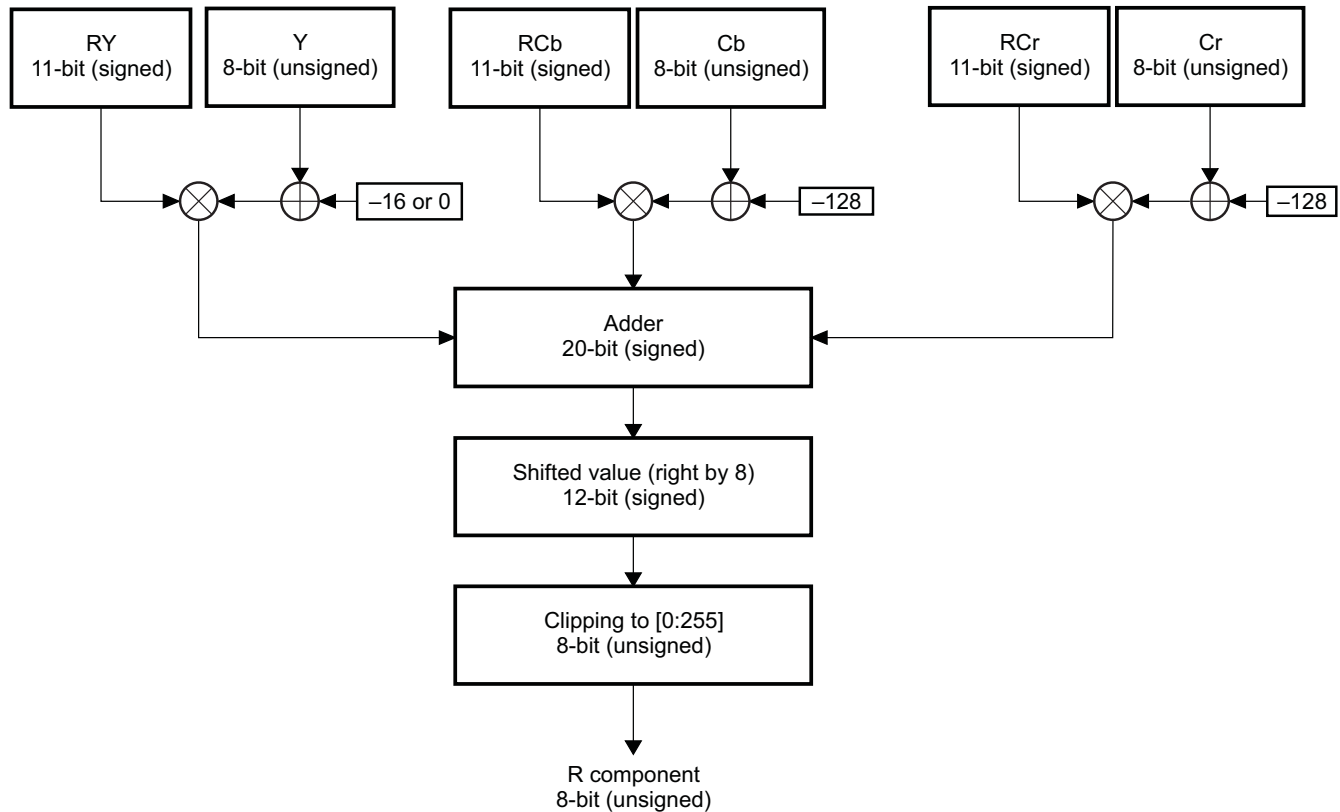

**Figure 1-76. YCbCr to RGB Registers (VIDFULLRANGE=1)**

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

[Figure 1-77](#) describes the computation for the calculation of the R component. The same computation applies for the G and B components:

**Figure 1-77. Color Space Conversion Macro-Architecture**

dss-065

#### 1.4.2.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

#### 1.4.2.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV422 (RGB12 and all the alpha formats like ARGB and RGBA are not supported). The user must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently (R, G, and B).

For the horizontal up-/downsampling, the equation is (R component with five taps):

$$R_{out}(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E066

(1-1)

For the vertical up-/downsampling, the equation is (R component with three taps):

$$R_{out}(n) = \left( \sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E067

(1-2)

For the vertical up-/downsampling, the equation is (R component with five taps):

$$R_{out}(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E068

(1-3)

*R<sub>out</sub>*: R component output

*C<sub>i</sub>(Φ)*  
dss-E069 : FIR filter coefficients

*R<sub>in</sub>*: R component input

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

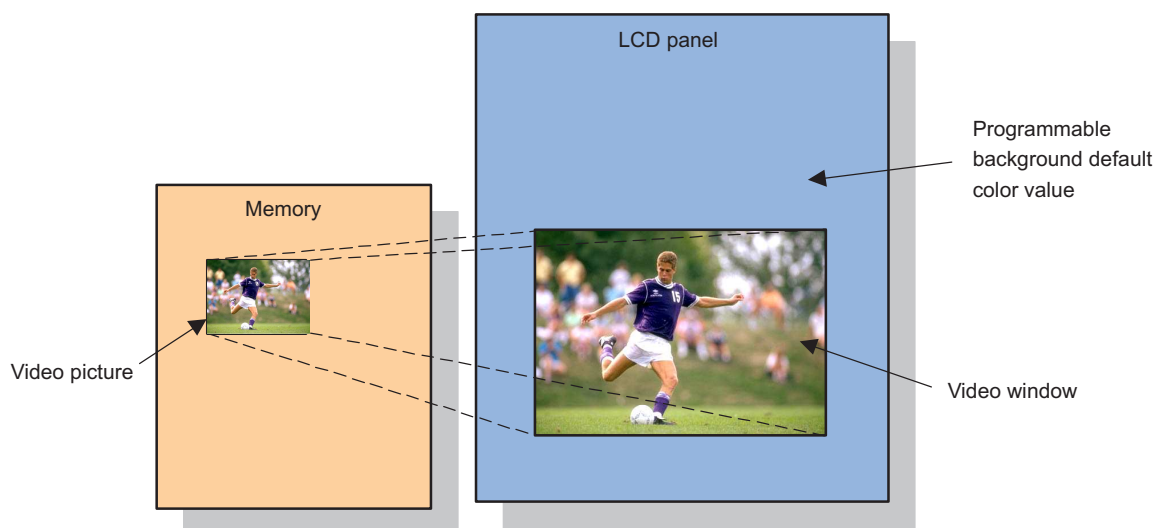

---

**Note:** The coefficients *C<sub>i</sub>(Φ)* depend on the phase between input and output pixels.

---

Figure 1-78 shows an example of video upsampling.

**Figure 1-78. Video Upsampling**

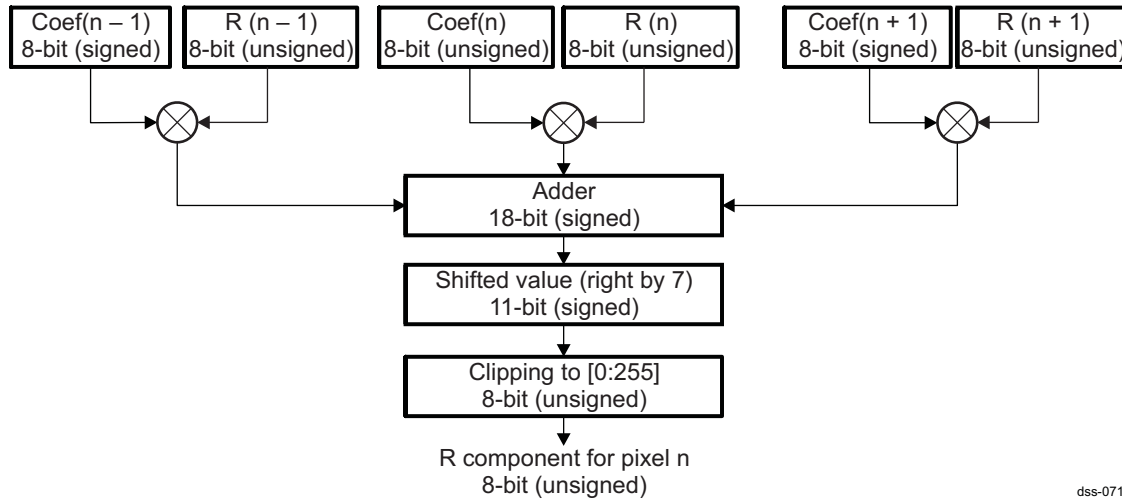

dss-070

### Filter Description

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is /2. The downsampling ratio using 5-tap configuration is /4. The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. Figure 1-79 shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

**Figure 1-79. Resampling Macro-Architecture (3-Coefficient Processing)**

dss-071

To determine if the minimum functional clock matches the down sampling ratio and the desired Pixel clock, the following formula must be used in conjunction with [Table 1-23](#) and [Table 1-24](#).

**Ratio V when performing a vertical down-sampling only**

$$h\_ratio = \frac{DISPC\_LCD\_SIZE.PPL}{DISPC\_VID\_SIZE.VidSizeX}$$

$$v\_ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.VidOrgSizeY}{DISPC\_VID\_SIZE.VidSizeY}$$

$$Ratio = \frac{v\_ratio}{2 \times h\_ratio} \quad \text{If } 1 < v\_ratio \leq 2$$

$$Ratio = \max\left(\frac{v\_ratio}{2 \times h\_ratio}, \frac{v\_ratio - 2}{2 \times (h\_ratio - 1)}\right) \quad \text{If } 1 < v\_ratio \leq 4$$

dss\_swpu108-E135

**Ratio H when performing a horizontal down-sampling only**

$$Ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.VidOrgSizeX}{DISPC\_VID\_SIZE.VidSizeX}$$

dss\_swpu108-E136

**Ratio H+V when performing a horizontal and vertical down-sampling**

Ratio = max (horizontal Ratio, vertical Ratio) as previously defined.

**Table 1-23. Functional Clock Frequency Requirement in RGB16 & YUV422—Active Matrix Display**

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

**Table 1-24. Functional Clock Frequency Requirement in RGB24—Active Matrix Display**

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	2xRatioxPCLK	2xRatioxPCLK	2xRatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

#### Use case example:

An input picture of 1024\*768 is scaled to an output picture of size of 800\*600 and displayed onto a LCD of resolution 1280\*768 at a PCLK of 74.25 MHz with a DSS functional clock of 133 MHz.

In this example, a H+V down-sampling is done on the input picture. Firstly the Ratio V and H are determined and the resulting maximum value is taken to calculate the functional clock frequency required.

**Ratio V:**  $h\_ratio = 1.6$  and  $v\_ratio = 1.28$  then Ratio = 0.4

**Ratio H:** Ratio = 1.28

**Ratio H+V:** Ratio =  $\max(1.28, 0.4) = 1.28$

In this use case, the horizontal and vertical down sampling range are 1:1–1:2. The 3-tap or 5-tap configuration can be taken into consideration. Therefore, from [Table 1-23](#) and [Table 1-24](#), If in RGB16-YUV422:

- 3-taps → DSS functional clock =  $4 * PCLK = 297$  MHz
- 5-taps → DSS functional clock = Ratio \* PCLK = 95.36 MHz

If in RGB24,

- 3-taps → DSS functional clock =  $4 * PCLK = 297$  MHz
- 5-taps → DSS functional clock =  $2 * Ratio * PCLK = 190.72$  MHz

In this use case, the pixel format supported is RGB16-YUV422 in a 5-tap configuration.

#### 1.4.2.4 Overlay Support

##### CAUTION

Enabling overlay optimization (setting the DSS.DISPC\_CONTROL [12] OVERLAYOPTIMIZATION bit) if no overlay region effectively exists (the DSS.DISPC\_VIDn\_ATTRIBUTES [0] VIDENABLE bit is cleared, with n = 1, 2) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFXWINDOWSKIP field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see [Figure 1-82](#)).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manger is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

##### 1.4.2.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

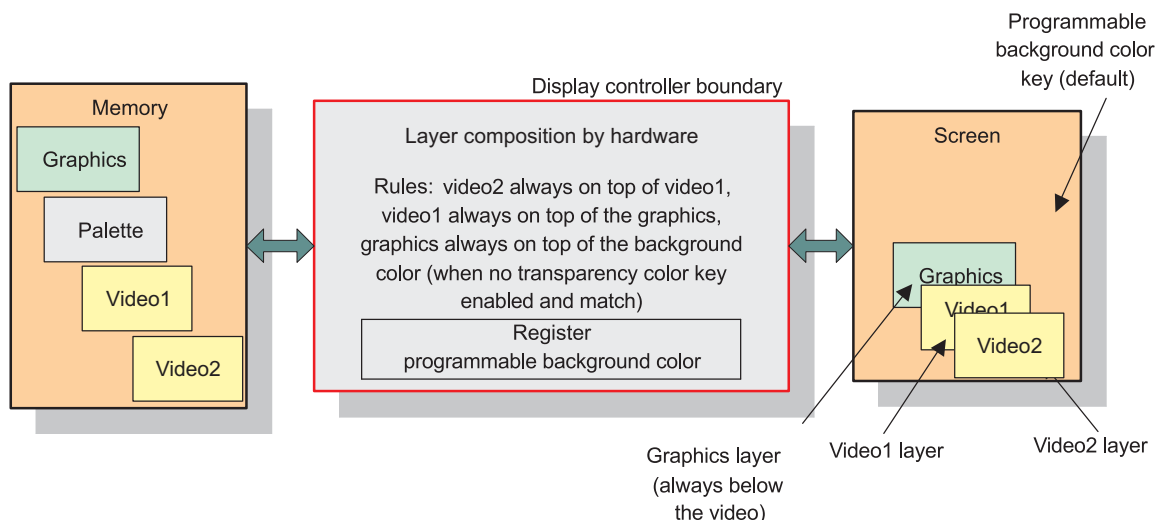

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

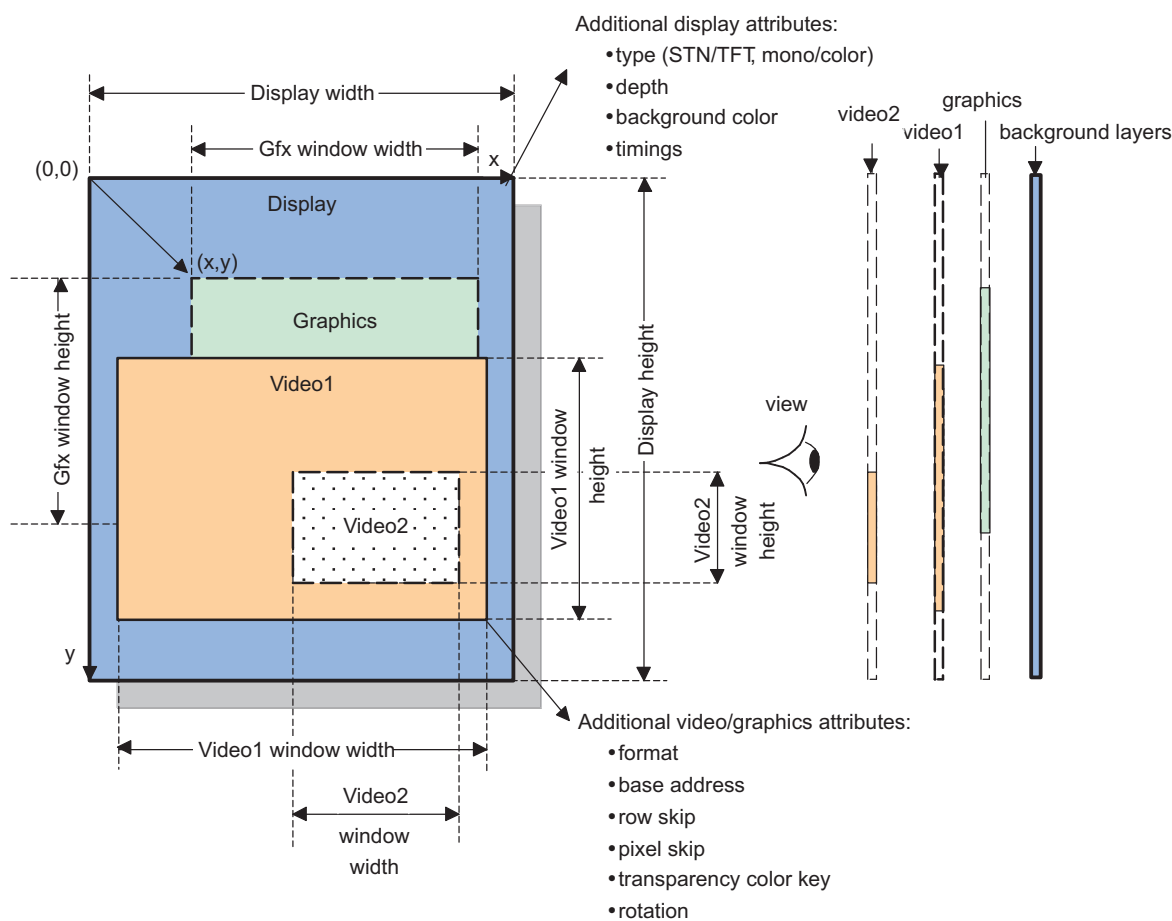

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 1-84](#)).

**Figure 1-80. Overlay Manager in Normal Mode**

dss-072

**Figure 1-81. Display Attributes in Normal Mode**

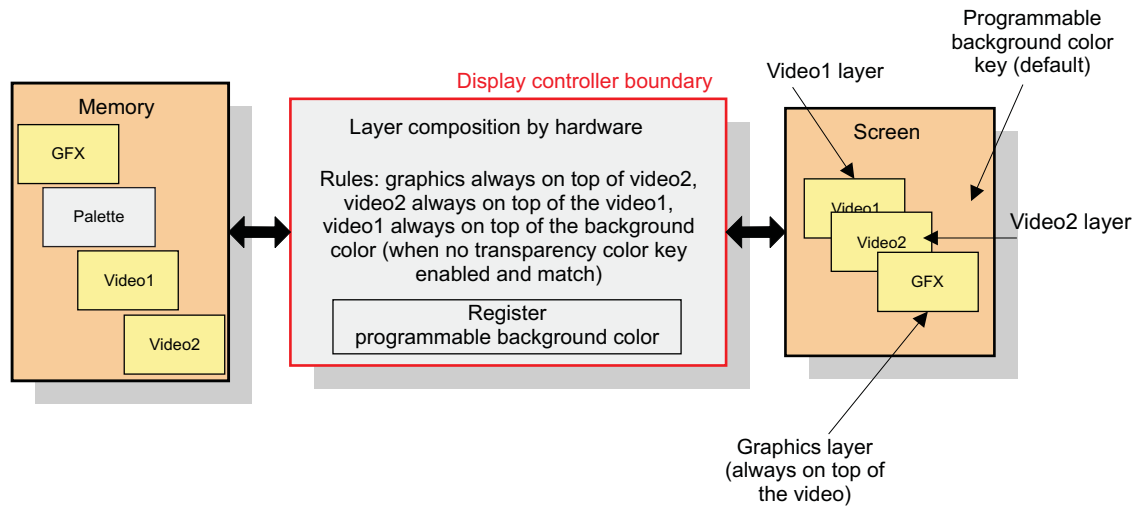

dss-073

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 1-84](#)).

**Figure 1-82. Overlay Manager in Alpha Mode**

dss-163

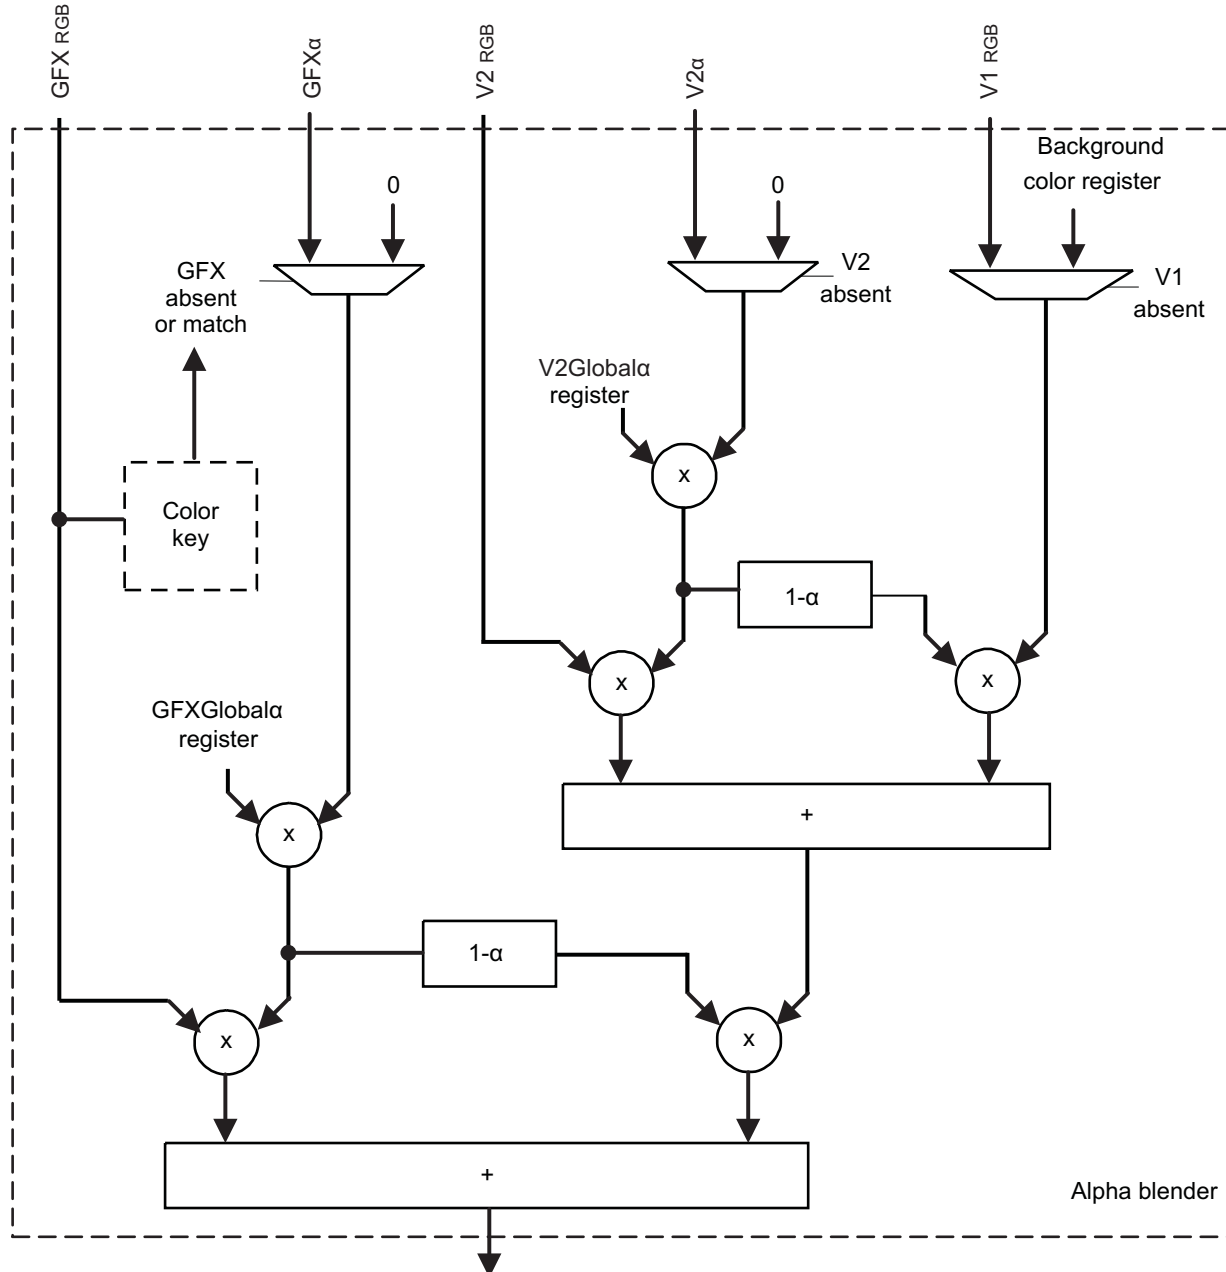

**Figure 1-83. Display Attributes in Alpha Mode**

dss-164

Figure 1-84 shows the alpha blending processing in detail.

Figure 1-84. Alpha Blending Macro Architecture

dss-165

**Note:** "1-alpha" operator corresponds to the basic 1's complement operation.

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. [Table 1-25](#) details the alpha blending 4-bit values and the corresponding blending percentage.

**Table 1-25. Alpha Blending 4-Bit Values**

Alpha Blending 4-Bit Value (ARGB-444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x00	100% (transparent)
0x1	0x11	93.33%
0x2	0x22	86.6%
...	...	...
0xE	0xEE	6.6%
0xF	0xFF	0% (opaque)

#### 1.4.2.4.2 Transparency Color Keys

##### 1.4.2.4.2.1 Normal mode

- The following features are available in normal mode:

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

---

**Note:** The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

---

- Video source transparency color key value

The video source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

The video source transparency color key can be used only if the color space conversion and the up-/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

To enable the video source transparency color key, set to 0x1 the DSS.DISPC\_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC\_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC\_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC\_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 1-85](#): The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying layers are shown.

**Figure 1-85. Video Source Transparency Example**

dss-074

- Graphics destination transparency color key value  
The Graphics destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen and the pixels different from the transparency color key are displayed over the video layers. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.  
To enable the graphics destination transparency color key, set to 0x0 the DSS.DISPC\_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC\_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC\_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC\_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.  
An example is shown in [Figure 1-86](#): The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

**Figure 1-86. Graphics Destination Transparency Example**

dss-075

#### 1.4.2.4.2.2 Alpha Mode

- The following features are available in alpha mode:  
Only the graphics source transparency color key is available. The encoded graphics pixel color value is compared to the transparency color key. The encoded pixel values with the source transparency key are not visible and the under-layer encoded pixel values or solid background color are visible. To enable the graphics source transparency color key, set to 0x0 the DSS.DISPC\_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC\_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC\_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC\_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

#### 1.4.2.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV422, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV422 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

#### 1.4.2.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Passive matrix technology

##### 1.4.2.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in [Figure 1-87](#).

**Figure 1-87. Color Phase Rotation Matrix**

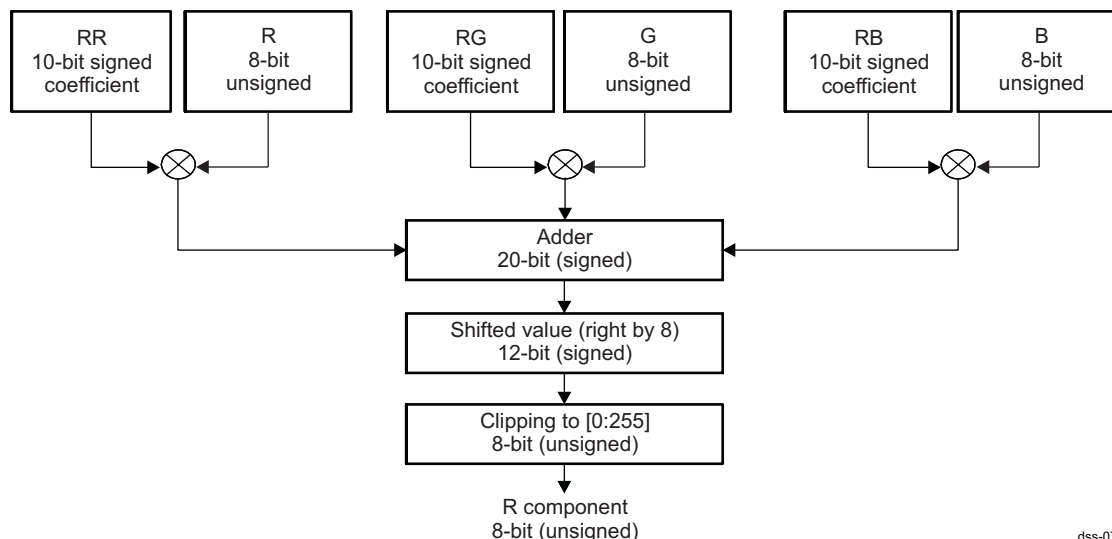

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix}$$

dss-E076

Figure 1-88 shows the color phase rotation macro-architecture.

**Figure 1-88. Color Phase Rotation Macro Architecture**

dss-077

#### 1.4.2.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- **Passive Matrix Technology:** The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of the spatial/temporal dithering logic is RGB 12-bit (not configurable).
- **Active Matrix Technology:** The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

#### 1.4.2.5.2 Passive Matrix Display Dithering Logic

- **Passive matrix technology**  
After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data. These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.
- **Active matrix technology**  
The passive matrix dithering logic is always bypassed in active displays.

---

**Note:** If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

---

#### 1.4.2.5.3 Passive Matrix Display Output FIFO

- Passive matrix technology  
The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.
- Active matrix technology  
The output FIFO is bypassed in active matrix mode.

#### 1.4.2.5.4 Multiple Cycle Output Format

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see [Table 1-26](#)):

- The DSS.DISPC\_CONTROL[24:23] TDMCYCLEFORMAT field is set to 0x2 (three cycles for one pixel).
- The DSS.DISPC\_DATA\_CYCLEk (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.DISPC\_DATA\_CYCLEk (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).
- The DSS.DISPC\_DATA\_CYCLEk (k=3) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

**Table 1-26. 8-Bit Interface Configuration/24-Bit Mode**

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[7]	R0[7]	G0[7]	B0[7]
Data[6]	R0[6]	G0[6]	B0[6]
Data[5]	R0[5]	G0[5]	B0[5]
Data[4]	R0[4]	G0[4]	B0[4]
Data[3]	R0[3]	G0[3]	B0[3]
Data[2]	R0[2]	G0[2]	B0[2]
Data[1]	R0[1]	G0[1]	B0[1]
Data[0]	R0[0]	G0[0]	B0[0]

#### 1.4.2.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). [Table 1-27](#) lists the maximum width depending on the TAP configuration and the pixel format.

**Table 1-27. Maximum Width Allowed**

Vertical Tap	Pixel Format	Maximum Width (Pixels)
3	RGB16	2048
	RGB24	
	YUV422	
5	RGB16	1024
	RGB24	
	YUV422	

#### 1.4.2.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

#### 1.4.2.8 Multiple Buffer Support

The user updates the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

#### 1.4.2.9 Rotation

In case of SDRAM buffer, the display controller accesses the encoded pixels in burst, always considering the consecutive data in memory. The rotation engine (VRFB) in the SDRAM scheduler (SDRC) is in charge of translating the addresses from virtual to physical SDRAM addresses (see the *Memory Subsystem* chapter).

---

**Note:** It is highly recommended to use the VRFB Rotation engine when possible and not the Display Subsystem DMA engine for rotating frame buffer to have a good performance in the L3 interconnect and SDRAM memory efficiency.

---

The rotation using the SMS-VRFB rotation engine is supported for BITMAP8, RGB12 (16-bit container) and ARGB16, RGB16, ARGB16, RGB24 (using 32-bit container) and ARGB32 and RGBA32 and YUV422 (YUV2 and YUYV) . The formats not supported are BITMAP1, BITMAP2, BITMAP4 and RGB24 (using 24-bit container).

### 1.4.3 DSI Protocol Engine Functionalities

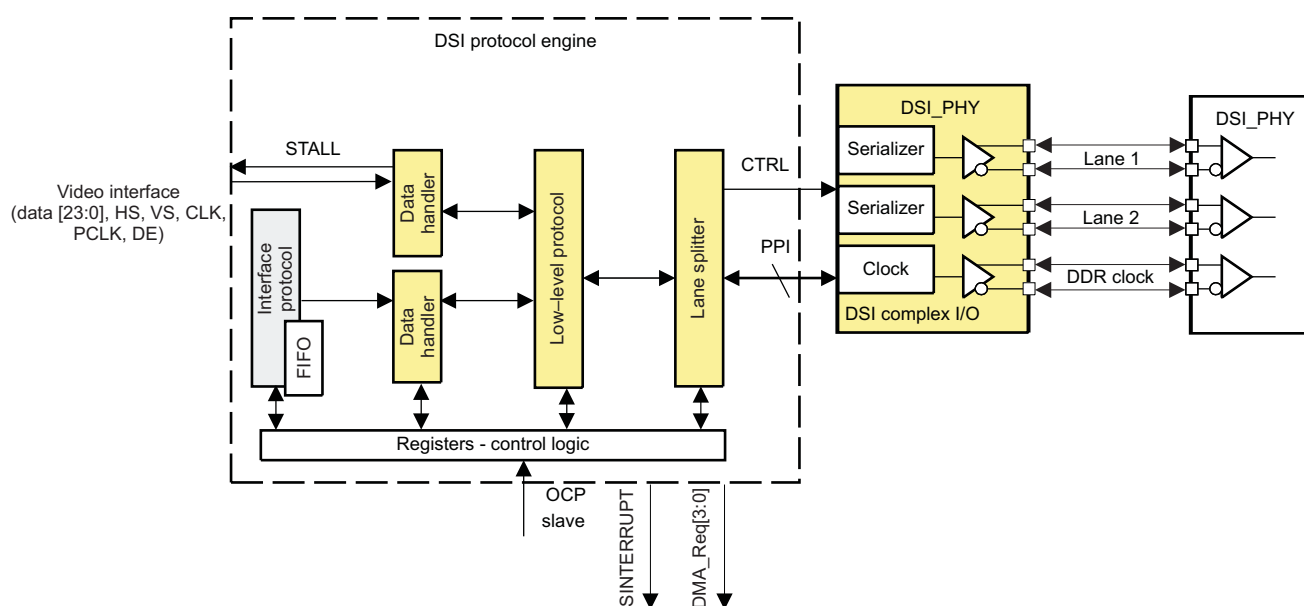

This section describes DSI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

The DSI protocol engine is based on the MIPI DSI specification v1.0. The DSI protocol engine integrates DSI interface to the display through the DSI\_PHY module, L4 interconnect interface and video interface from the display controller. The DSI\_PHY or complex I/O module is detailed in [Section 1.4.5](#). The interface between DSI protocol engine and DSI\_PHY is based on the PPI defined in the MIPI DSI\_PHY specification. For more details, please refer to MIPI DSI1.0 specification. The DSI Transmitter (Protocol Engine + PHY) port can be connected to multiple displays using a single DSI host port. The DSI protocol engine controls the DSI PLL Control module detailed in [Section 1.4.4](#). The DSI Transmitter port can be used in video mode or/and command mode.

### 1.4.3.1 DSI Protocol Architecture

The DSI protocol engine receives data from the video port and/or the L4 interconnect slave port, encapsulates them with the virtual channel id, generates the ECC and check-sum, and splits the data into byte stream to the DSI\_PHY to be sent using the Low speed (LS) or High speed (HS) protocol. The DSI protocol engine receives data and acknowledge from the display using the same DSI link in case of bi-directional display. Multiple data streams can be interleaved to support multiple panels connected to the same host DSI port. [Figure 1-89](#) details the DSI protocol engine architecture.

**Figure 1-89. DSI Protocol Engine**

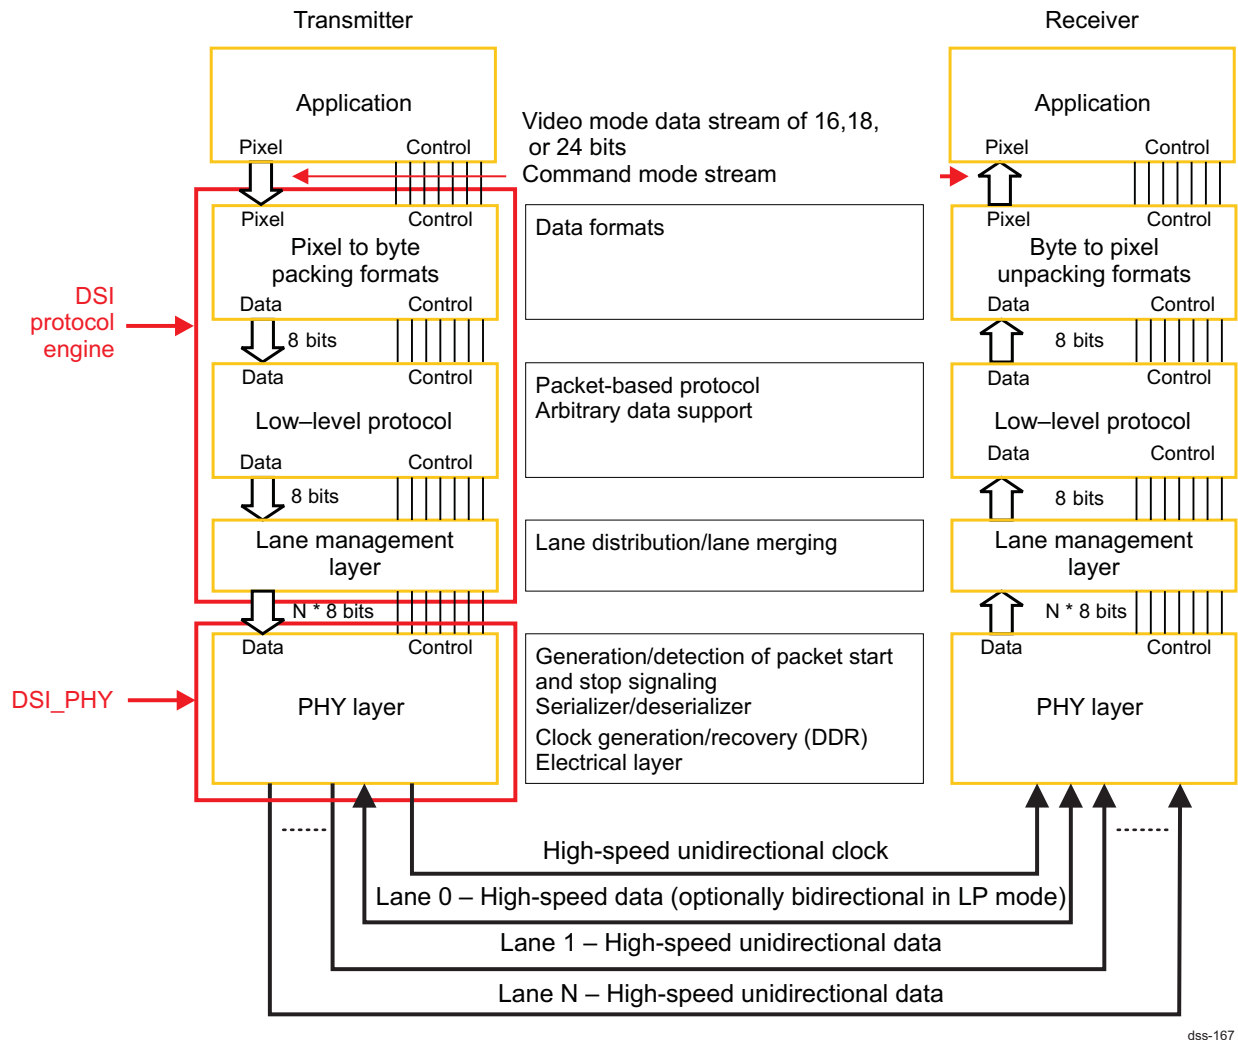

dss-166

**Note:** The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be Clock or Data. The DSI complex I/O receives the configuration for pin order and the differential +/- in a pair from the settings in DSS.DSI\_COMPLEXIO\_CFG1 register.

The DSI serial interface is a bi-directional differential serial interface with data/clock for the physical layer (configured in unidirectional link in case the display module is only unidirectional). The maximum DSI data transfer capacity is 800 Mbps per channel. The speed of the link can be software configured only when the DSI\_PHY is in stop state or in ULPS.

[Figure 1-90](#) shows the DSI transmitter/receiver high-level data flow.

Figure 1-90. DSI Transmitter/Receiver Data Flow

dss-167

#### 1.4.3.2 Clock Requirements

The serial clock generated by the DSI host and sent to the display can be a continuous clock. The clock lane supports clock transmission even there is no data to send for displays that require continuous clock. It is software programmed through the DSS.DSI\_CLK\_CTRL[13] DDR\_CLK\_ALWAYS\_ON bit: This bit can be programmed only when the interface is disabled (that is, DSS.DSI\_CTRL[0] IF\_EN bit set to 0).

The peripheral can use two different kinds of clocks. The first one is the DDR clock provided on the clock lane. The second clock is some transitions on the data lane 1 even if there is no valid data to send using low power mode.

The LP clock (TxClkEsc) frequency provided to the DSI complex I/O is in the range of 67% to 150% of the peripheral Low-Power (LP) clock frequency. It is generated internally by the DSI protocol engine module using the DSI functional clock. The DSI functional clock is divided by 1, 2, 3, up to 8191 using the value programmed in the DSS.DSI\_CLK\_CTRL[12:0] LP\_CLK\_DIVISOR field. The LP clock generated from DSI functional clock should be in the range of 20 MHz down to 32 KHz. The duty cycle should be 50/50 (tolerance of 45/55 for maximum value).

The DSS.DSI\_CLK\_CTRL[20] LP\_CLK\_ENABLE bit is used to enable or disable the clock. When disabled, the value of DSS.DSI\_CLK\_CTRL[12:0] LP\_CLK\_DIVISOR field is ignored and does not need to be programmed by the software user.

### 1.4.3.2.1 Timing Parameters for an LP to HS Transaction

Figure 1-91 shows the timing requirement when switching the data and clock lane state from LP to HS. Table 1-28 lists the LP to HS timing parameters.

**Figure 1-91. LP to HS Timing**

dss-325

**Table 1-28. LP to HS Timing Parameters**

Timing	Description	Register
$T_{LPX}$	Length of any low-power state period. The value set in DSI_PHY_CFG1[22:16] TLPX_HALF bit field is half of the $T_{LPX}$ .	DSI_PHY_CFG1[22:16] TLPX_HALF
$T_{CLK-PREPARE}$	Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission	DSI_PHY_CFG2[7:0] TCLK_PREPARE
$T_{CLK-ZERO}$	Time to drive the CLK lane to HS-0 state before starting the clock	DSI_PHY_CFG1[7:0] TCLK_ZERO
$T_{CLK-PRE}$	Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode $T_{CLK-PRE} = DDR\_CLK\_PRE - T_{LPX} - T_{CLK-PREPARE} - T_{CLK-ZERO}$	See the MIPI DSI_PHY specification.
$T_{HS-PREPARE}$	Time to drive the data lane to LP-00 state, to prepare for HS packet transmission	DSI_PHY_CFG0[31:24] THS_PREPARE
$T_{HS-ZERO}$	Time to drive the data lane to HS-0 state before the synchronous sequence. $T_{HS-ZERO} = DSI\_PHY\_CFG0[23:16] THS\_PREPARE\_THS\_ZERO - T_{HS-PREPARE}$	DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO

**Table 1-28. LP to HS Timing Parameters (continued)**

Timing	Description	Register
DDR_CLK_PRE	Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS	DSI_CLK_TIMING[15:8] DDR_CLK_PRE
ENTER_HS_MODE_LATENCY	Time to enter into HS mode. It is critical that $\text{ENTER\_HS\_MODE\_LATENCY} = 1 + \text{DIVROUNDUP}(2 * \text{TLPX\_HALF}, 4) + \text{DIVROUNDUP}(\text{THS\_PREPARE}, 4) + \text{DIVROUNDUP}(\text{THS\_PREPARE\_THS\_ZERO} - \text{THS\_PREPARE} + 3, 4)$ <sup>(1)</sup>	DSI_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY

<sup>(1)</sup> The formula  $\text{DIVROUNDUP}(\text{value}, \text{div})$  is equivalent to  $\text{ROUNDUP}(\text{value}/\text{div})$ .

#### 1.4.3.2.2 Timing Parameters for an HS to LP Transaction

Section 1.4.3.2.3 shows the timing requirement when switching the state of the data and clock lanes from HS to LP.

dss-326

**Table 1-29. HS to LP Timing Parameters**

Timing	Description	Register
$T_{HS-EOT}$	If EoT is enabled, a delay is added to EXIT_HS_MODE_LATENCY to send the EoT packet. The EoT period depends on the number of data lanes: 1 data lane = 4 DDR clocks 2 data lanes = 2 DDR clocks	
$T_{HS-TRAIL}$	Time to drive flipped differential state after last payload data bit of a HS transmission burst	DSI_PHY_CFG0[15:8] THS_TRAIL
$T_{HS-EXIT}$	Time to drive data lane to LP-11 state, after HS burst	DSI_PHY_CFG0[7:0] THS_EXIT
$T_{CLK-POST}$	Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode	See the MIPI DSI_PHY specification.
$T_{CLK-TRAIL}$	Time to drive HS differential state after last payload clock bit of a HS transmission burst	DSI_PHY_CFG1[15:8]TCLK_T RAIL
DDR_CLK_POST	Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: $DDR\_CLK\_POST \geq T_{HS-TRAIL} + T_{HS-EXIT} + T_{CLK-POST}$	DSI_CLK_TIMING[7:0] DDR_CLK_POST
EXIT_HS_MODE_LATENCY	Time to exit in HS mode. It is critical that $EXIT\_HS\_MODE\_LATENCY = DIVROUNDUP((T_{HS-TRAIL} + T_{HS-EXIT}), 4) + 1 + T_{HS-EOT}^{(1)}$	DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY

(1) The formula  $DIVROUNDUP(value, div)$  is equivalent to  $ROUNDUP(value/div)$ .

#### 1.4.3.2.4 Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last low speed transfer. The same value is used for all the virtual channels sending packets in low speed mode.

The size of the payload is defined by the DSS.DSI\_CLK\_CTRL[17:16] LP\_CLK\_NULL\_PACKET\_SIZE field. The header value depends on the virtual channel (VC) ID and the size of the payload as detailed in [Table 1-30](#) and [Table 1-31](#).

**Table 1-30. Extra NULL Packet Header**

Virtual Channel ID	Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE)	Header (1st byte)	Header (2nd byte): WC LSB	Header (3rd byte): WC MSB	Header (ECC)
0x0	0	0x9	0x0	0x0	0x9
	1		0x1		0x13
	2		0x2		0x2F
	3		0x3		0x35
0x1	0	0x49	0x0		0x1F
	1		0x1		0x05
	2		0x2		0x39
	3		0x3		0x23
0x2	0	0x89	0x0		0x10
	1		0x1		0x0A
	2		0x2		0x36
	3		0x3		0x2C
0x3	0	0xC9	0x0		0x06
	1		0x1		0x1C
	2		0x2		0x20

**Table 1-30. Extra NULL Packet Header (continued)**

Virtual Channel ID	Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE)	Header (1st byte)	Header (2nd byte): WC LSB	Header (3rd byte): WC MSB	Header (ECC)
	3		0x3		0x3A

**Table 1-31. Extra NULL Packet Payload**

Payload size (DSI_CLK_CTRL[17:16] LP_NULL_PACKET_SIZE)	Payload (1st byte)	Payload (2nd byte)	Payload (3rd byte)	Payload (CRC) LSB	Payload (CRC) MSB
0	NA	NA	NA	0xFF	0xFF
1	0	NA	NA	0x87	0x0F
2	0	0	NA	0xB8	0xF0
3	0	0	0	0x33	0x39

**Notes:**

- In [Table 1-30](#) and [Table 1-31](#), both ECC and checksum are enabled
- NA stands for not available

### 1.4.3.3 DSI Transfer Modes

There are two transfer modes supported by the DSI module:

- Video mode (VM): Pixels are received from the video port, there are some real time constraints (pixels should be sent at the pixel frequency required by the display module) for sending the data to the display;
- Command mode (CM): Pixels can be received from the video port or from the L4 interconnect, there are no real time constraints except that tearing effect should be avoided by starting the transfer at the right time during scan of the display and should be fast enough.

#### 1.4.3.3.1 Video Mode

The video mode refers to the MIPI DPI standard. The sync events and pixels should be sent according to the display mode timings. Data are received from the video port. The display controller is in charge of fetching the data from the system memory and providing the data to the DSI protocol engine using the video port. The short packets used for the sync event are using precalculated 32-bit values. The long packets are constructed using the header defined in DSS.DSI\_VCn\_LONG\_PACKET\_HEADER registers.

#### 1.4.3.3.2 Command Mode

The command mode refers to the MIPI DCS standard. The commands, parameters and pixels are sent to the display module with limited real time constraints (as defined in [Section 1.4.3.3.1](#)). The pixels can be provided on the video port by the display controller or on the L4 interconnect port.

**Note:** In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC\_CONTROL[11] STALLMODE bit to 1.

The DSS.DSI\_VCn\_LONG\_PACKET\_HEADER registers are used for the header of long packets, the DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER registers are used for the short packets.

The Error Correction Code (ECC) can be provided while writing the ECC value directly into the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER and DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER registers. The DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN field indicates if the ECC value should be calculated or if the value written in the register should be used instead for command and video modes. In case of synchronization short packets for video mode, since the hardware generates the short packets without using DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER registers, if the DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN field is set to 1, the ECC is calculated otherwise the value zero is used. The feature is used to generate incorrect ECC for debug purpose and to ease the check for the link and peripheral error detection and correction.

For the payload, the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD registers are used. Each 32-bit PAYLOAD data is written into the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register from the MPU subsystem or system DMA. It is buffered to be able to send packets with higher rate than the L4 interconnect frequency can provide. The word count defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER registers is used to determine the number of bytes to be sent using the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD registers. The write into the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER registers is required before accessing the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register. The hardware should be able to extract the length of the payload and be able to discard extra data sent using the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register. The hardware takes into account the write into the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register only if the virtual channel is enabled otherwise the write is ignored by hardware.

In the case of pixels received on the video port, only the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register is used. The video port pixels are used for the payload.

#### 1.4.3.3.3 Video + Command Modes

The two modes can be interlaced to send two DSI streams to two types of panels: Video or command types. The number of concurrent video stream is limited to a single one. The number of concurrent command mode streams is limited to 4 when there is no video stream and 3 otherwise. In case there is one DSI stream using video mode, the command mode pixels should be provided on the L4 interconnect only.

#### 1.4.3.3.4 Burst Modes

- Frequency-burst mode The frequency-burst mode is used to reduce the High-Speed (HS) period by increasing the clock frequency on the DSI link. It allows in some case, the power consumption reduction of the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine needs to buffer a full line before sending the HS packets for the line. A double buffering mechanism is required to be able to send a line while the following one is being received on the video port.
- Transparent-burst mode The transparent-burst mode is used by increasing the pixel clock frequency generated by the display controller with in addition an increase of the horizontal blanking period.

#### 1.4.3.3.5 Interleaving Mode

Video mode can output command mode packets, which are provided to DSI through the L4 interconnect, during the blanking periods of the video stream sequence on the PPI link. These command mode packets can be programmed as high-speed packets or low-power packets.

During a video stream sequence on the PPI link, four types of gap exist:

- BLLP gap: Blanking period during VSA, VBP, and VFP lines.
- HSA gap: Blanking period during VACT lines; always between HS and HE short packet.
- HBP gap: Blanking period during VACT lines; always between HS/HE short packet and data pixel long packet.
- HFP gap: Blanking period during VACT lines; always between data pixel long packet and the end of the current VACT line.

To perform interleaving in a particular gap, video mode must be set to go into low-power state during the blanking gap. Each type of gap has separate configurable register bits that determine whether a blanking long packet will be sent or the link will go into low-power state during the gap on the PPI link. If low-power state is set during a gap, the DSI module performs interleaving during that period.

Two set of registers are available for:

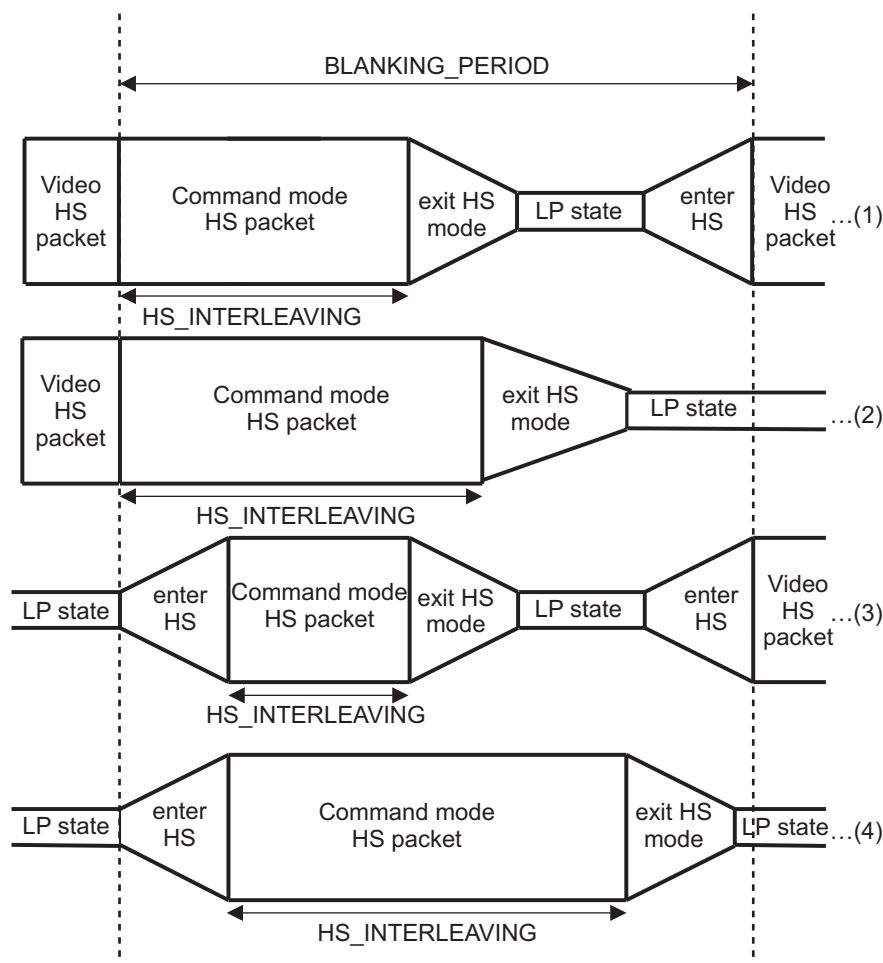

- High-speed interleaving (when high-speed command mode packets must be sent during a video stream on the PPI link).
- Low-power interleaving (when low-power command mode packets must be sent during a video stream on the PPI link).

#### 1.4.3.3.5.1 HS Command Mode Interleaving Programming Model

[Figure 1-92](#) shows the various HS mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in HS command mode packets.

- The BL\_HS\_INTERLEAVING[31:16] DSI\_VM\_TIMING6 bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during a BLLP gap.
- The HBP\_HS\_INTERLEAVING[7:0] DSI\_VM\_TIMING4 bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HBP gap.
- The HFP\_HS\_INTERLEAVING[15:8] DSI\_VM\_TIMING4 bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- The HSA\_HS\_INTERLEAVING[23:16] DSI\_VM\_TIMING4 bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for the clock and data lane to enter and exit HS mode latency. According to the scenario, different equations must be considered when calculating the register values.

**Figure 1-92. HS Command Mode Interleaving**

dss-327

**Note:** For calculations and equations, the following abbreviations are used: EXIT\_CLK\_HS\_MODE represents the exit HS mode latency for the clock lane. There is no dedicated register for this value but the programmer must know this value for further calculations.  

$$\text{EXIT\_CLK\_HS\_MODE} = T_{\text{CLK-TRAIL}} + T_{\text{HS-EXIT}}$$

For the following equations, BLANKING\_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The HS\_INTERLEAVING period represents the maximal period HS command mode packets. Its value is set in the BL\_HS\_INTERLEAVING, HSA\_HS\_INTERLEAVING, HBP\_HS\_INTERLEAVING, or HFP\_HS\_INTERLEAVING registers, depending on the blanking type.

In each scenario, two calculations are present, depending on the value of ddr\_clk\_always\_on.

- ddr\_clk\_always\_on = 1: Clock lane is always active.
- ddr\_clk\_always\_on = 0: Clock lane is activated only when there are HS packets to be sent on the PPI link.
- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
  - ddr\_clk\_always\_on = 1  

$$\text{HS\_INTERLEAVING} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$
  - ddr\_clk\_always\_on = 0  

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$

$$\text{HS\_INTER2} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_POST} + \text{EXIT\_CLK\_HS\_MODE} + \text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + 1)$$

$$\text{HS\_INTERLEAVING} = \min\{\text{HS\_INTER1}, \text{HS\_INTER2}\}$$

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.
  - $\text{ddr\_clk\_always\_on} = 1$   

$$\text{HS\_INTERLEAVING} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + 3)$$
  - $\text{ddr\_clk\_always\_on} = 0$   

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + 3)$$

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_POST} + \text{EXIT\_CLK\_HS\_MODE} + 3)$$

$$\text{HS\_INTERLEAVING} = \min\{\text{HS\_INTER1}, \text{HS\_INTER2}\}$$
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
  - $\text{ddr\_clk\_always\_on} = 1$   

$$\text{HS\_INTERLEAVING} = \text{BLANKING\_PERIOD} - (\text{ENTER\_HS\_MODE\_LATENCY} + \text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$
  - $\text{ddr\_clk\_always\_on} = 0$   

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + \text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$

$$\text{HS\_INTER2} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + \text{DDR\_CLK\_POST} + \text{EXIT\_CLK\_HS\_MODE} + \text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + 1)$$

$$\text{HS\_INTERLEAVING} = \min\{\text{HS\_INTER1}, \text{HS\_INTER2}\}$$
- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
  - $\text{ddr\_clk\_always\_on} = 1$   

$$\text{HS\_INTERLEAVING} = \text{BLANKING\_PERIOD} - (\text{ENTER\_HS\_MODE\_LATENCY} + \text{EXIT\_HS\_MODE\_LATENCY} + 3)$$
  - $\text{ddr\_clk\_always\_on} = 0$   

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + \text{EXIT\_HS\_MODE\_LATENCY} + 3)$$

$$\text{HS\_INTER2} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + \text{DDR\_CLK\_POST} + \text{EXIT\_CLK\_HS\_MODE} + 1)$$

$$\text{HS\_INTERLEAVING} = \min\{\text{HS\_INTER1}, \text{HS\_INTER2}\}$$

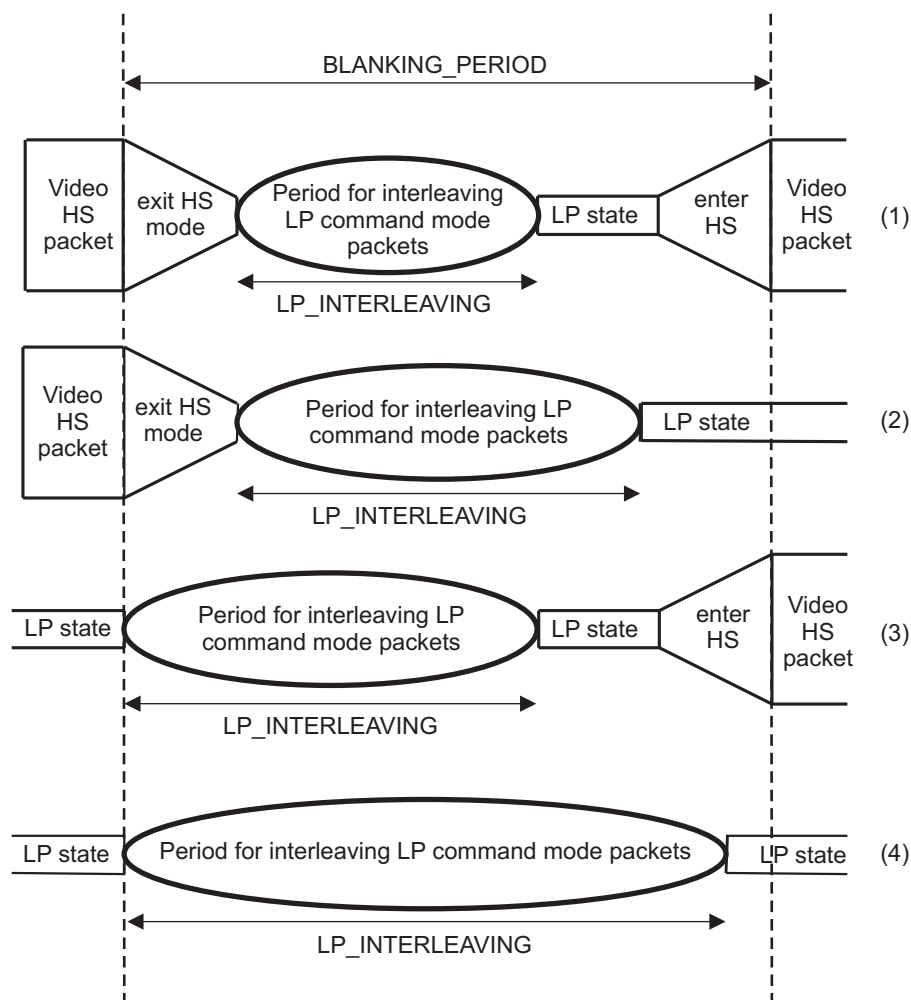

#### 1.4.3.3.5.2 LP Command Mode Interleaving Programming Model

Figure 1-93 shows the various LP mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in LP command mode packets.

- BL\_LP\_INTERLEAVING bit field DSI\_VM\_TIMING6[15:0] defines the number of TxByteClkHS clock cycles used to interleave the HS command mode packets during a BLLP gap.
- HBP\_LP\_INTERLEAVING bit field DSI\_VM\_TIMING5[7:0] defines the number of TxByteClkHS clock cycles used to interleave the HS command mode packets during an HBP gap.
- HFP\_LP\_INTERLEAVING bit field DSI\_VM\_TIMING5[15:8] defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- HSA\_LP\_INTERLEAVING bit field DSI\_VM\_TIMING5[23:16] defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for clock and data lane enter and exit LP mode latency. Clock lane timings do not affect LP command mode interleaving, because the clock lane can be controlled separately, compared with the data lane high-speed and low-power mutually exclusive control. Clock lanes can be in high-speed mode while the data lanes are in high-speed data transfer mode, low-power data transfer mode, or in low-power state.

According to this scenario, different equations must be considered for calculating register values.

**Figure 1-93. LP Command Mode Interleaving**

dss-328

For the following equations, **BLANKING\_PERIOD** represents the BLLP, HSA, HBP, or HFP blanking periods. The **LP\_INTERLEAVING** period represents the maximal period in LP command mode packets. Its value is set in the **BL\_LP\_INTERLEAVING**, **HSA\_LP\_INTERLEAVING**, **HBP\_LP\_INTERLEAVING**, or **HFP\_LP\_INTERLEAVING** registers, depending on the blanking type.

**ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP** represents the number of TxByteClkHS clock cycles during which LP interleaving can appear.

To calculate the **LP\_INTERLEAVING** value:

1. Calculate how many TxByteClkHS clock cycles can be reserved for LP interleaving during the appropriate blanking video mode gap.
2. Calculate the **LP\_INTERLEAVING** value according to the results of Step 1.

Step 1:

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.  

$$\text{ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$
- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.  

$$\text{ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + 1)$$
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.  

$$\text{ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP} = \text{BLANKING\_PERIOD} - (\max\{$$

ENTER\_HS\_MODE\_LATENCY, 2} + 1)

- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.

ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP = BLANKING\_PERIOD – 1

After finishing Step 1, the time period available for LP interleaving is known:

$T_{lp\_available} = \text{ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP} * T_{TxByteClkHS}$

Step 2:

The resulting value must be programmed in the appropriate video mode register for LP interleaving.

$$LP\_INTERLEAVING < \left\lceil \frac{T_{lp\_available} - 8 * T_{hsbyte\_clk} - 5 * T_{dsif\_clk}}{T_{txclkesc}} - 26 \right\rceil$$

dss-E124

$T_{TxByteClkHS}$ : Period of HS byte clock of DSI\_PHY module

$T_{dsif\_clk}$ : Period of DSI functional clock

$T_{txclkesc}$ : Period of LP transmit escape clock

#### 1.4.3.4 Power Management

The DSI protocol engine implements an handshake protocol on its L4 interconnect port with the PRCM. The DSI protocol engine provides a clock gating signal CIO\_CLK\_ICG to gate the L3 interface clock (L3\_ICLK) provided by the PRCM to the DSI complex I/O. It allows reduction of the power consumption of the DSI complex I/O while the DSI link is not in used. To gate the L3\_ICLK clock at DSI complex I/O level, set the DSS.DSI\_CLK\_CTRL[14] CIO\_CLK\_ICG bit to 1.

#### 1.4.3.5 Serial Configuration Port (SCP) Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL Control module and to the DSI complex I/O. It spends several cycles to serialize the data to be sent. Software users should take into account the delay in processing the transfer of the data from/to the slave port to/from the module.

##### 1.4.3.5.1 Shadowing Register

The two first SCP registers for the DSI complex I/O address map should be implemented as shadow registers. The shadowing mechanism is enabled/disabled using the DSS.DSI\_COMPLEXIO\_CFG1[31] SHADOWING bit:

- When setting the DSS.DSI\_COMPLEXIO\_CFG1[31] SHADOWING bit to 1, the transfer of the values from the two first L4 interconnect port registers into the two first registers of the DSI complex I/O (DSS.DSI\_PHY\_CFG0 and DSS.DSI\_PHY\_CFG1) is done only when the DISPC\_UPDATE\_SYNC signal from the display controller is active and the DSS.DSI\_COMPLEXIO\_CFG1[30] GOBIT is set to 1. If there is no pending update for the two registers, when the DISPC\_UPDATE\_SYNC signal is asserted, the DSS.DSI\_COMPLEXIO\_CFG1[30] GOBIT bit is reset by hardware and there is no SCP transfer.
  - If there is only one register to update, only the corresponding new value is transferred. The second register in the DSI complex I/O is not updated. When the transfer is completed, the DSS.DSI\_COMPLEXIO\_CFG1[30] GOBIT is reset by hardware.
  - If the two registers need to be updated, the order of the transfer is first the register with lower address and then the second one. When the transfers are completed, the DSS.DSI\_COMPLEXIO\_CFG1[30] GOBIT is reset by hardware.

When there is an on-going transfer (read or write) to any SCP register, the transfer should complete prior to start the update of shadowing registers.

- When unsetting the DSS.DSI\_COMPLEXIO\_CFG1[31] SHADOWING bit to 0, if the transfer into the two first DSI complex I/O registers has already started, it should be finished

---

**Note:** When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending otherwise the values stored in the DSI complex I/O are returned.

---

#### 1.4.3.5.2 *Busy Signal*

The signal SCPBusy indicates that there is still some activity using the SCPClk provided by the PRCM. The SCPClk clock is the DSS\_L3\_ICLK clock.

#### 1.4.3.6 **Power Control**

The DSI protocol engine can control and send power commands for both DSI complex I/O and DSI PLL controller modules.

### 1.4.3.6.1 Complex I/O Power Control Commands

#### 1.4.3.6.1.1 Complex I/O Power Control Commands

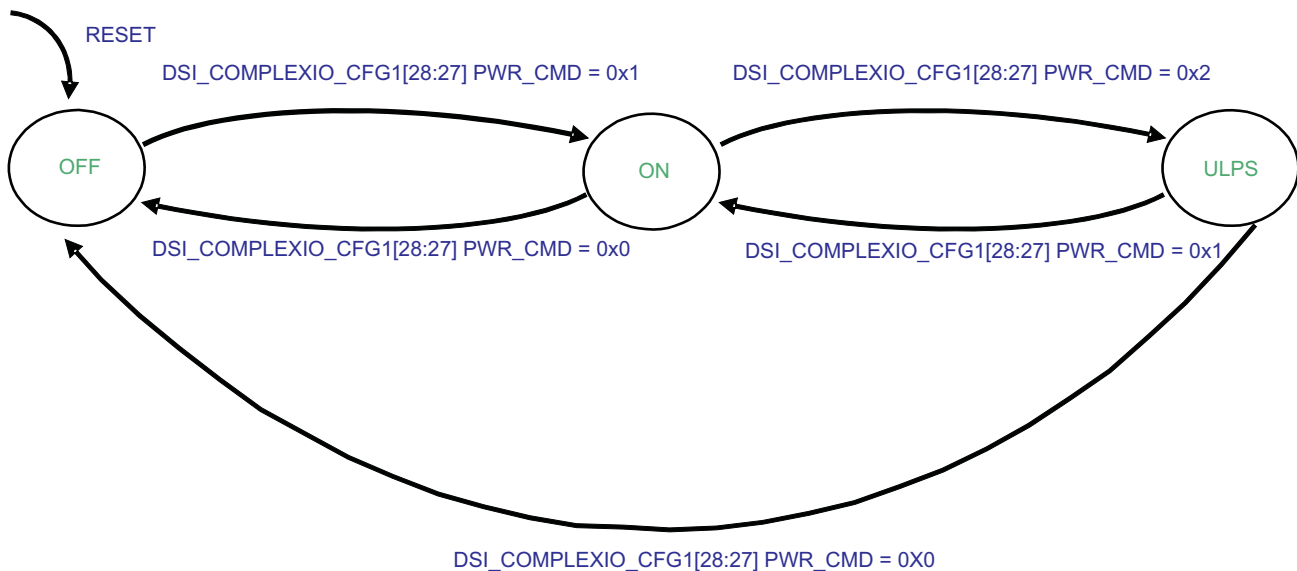

The DSI complex I/O can be set into three modes:

- **OFF:** In this power state, the complete DSI\_PHY circuit is powered down. The internal LDO is OFF.
- **ON:** In this power state, the complete DSI\_PHY circuit is powered on and functional.
- **Ultra Low Power State (ULPS):** In this power state, the ULPS exit detection circuit power switch is ON for the lanes which are in receive ULPS mode. For the lanes which are in transmit ULPS mode, the circuitry for weak pull-down is ON. The ultra low power state should only be used when all the three lanes are in ULPS (transmit or receive).

#### 1.4.3.6.1.2 Complex I/O Power FSM

Figure 1-94 describes the power control FSM to control the power state of the complex I/O.

**Figure 1-94. Complex I/O Power FSM**

dss-169

The PwrCmdOff, PwrCmdUlp and PwrCmdOn commands control the state transition of the DSI complex I/O. Software users should set the DSS.DSI\_COMPLEXIO\_CFG1[28:27] PWR\_CMD field to ask for a state change. The allowed transitions are: OFF -> ON and ON -> ULP and ULP -> OFF. The DSS.DSI\_COMPLEXIO\_CFG1[26:25] PWR\_STATUS field gives a status on the current state of the DSI complex I/O.

#### CAUTION

- In automatic mode, the software should ensure that the DSI complex I/O in the ON mode (that is, ON command already sent) before sending requests to the complex I/O.
- In a command request to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI complex I/O).
- To change state to ULP state, the user should ensure that all the three ULPSActiveNot signals are low. The ULPSActiveNot\_ALL0\_IRQ interrupt can be used by the software user to determine the state of the ULPSActiveNot signals. The change from ULP to ON state is required before starting the ULP exit sequence (refer to [Section 1.4.3.7.1](#) for details).

### 1.4.3.6.2 DSI PLL Power Control Commands

The DSI PLL controller module can be set into four modes:

- OFF: The DSI PLL and HSDIVIDER are OFF.
- ON ALL: Both DSI PLL and HSDIVIDER are ON. The HS\_CLK clock is provided to the DSI complex I/O and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The HS\_CLK clock is provided to the DSI complex I/O but the second clock output is not provided to the HSDIVIDER.
- ON DIV: Both DSI PLL and HSDIVIDER are ON. The HS\_CLK clock is not provided to the DSI complex I/O but the second clock output is provided to the HSDIVIDER.

#### 1.4.3.6.2.1 DSI-PLL Power FSM

Figure 1-95 shows the DSI PLL power FSM.

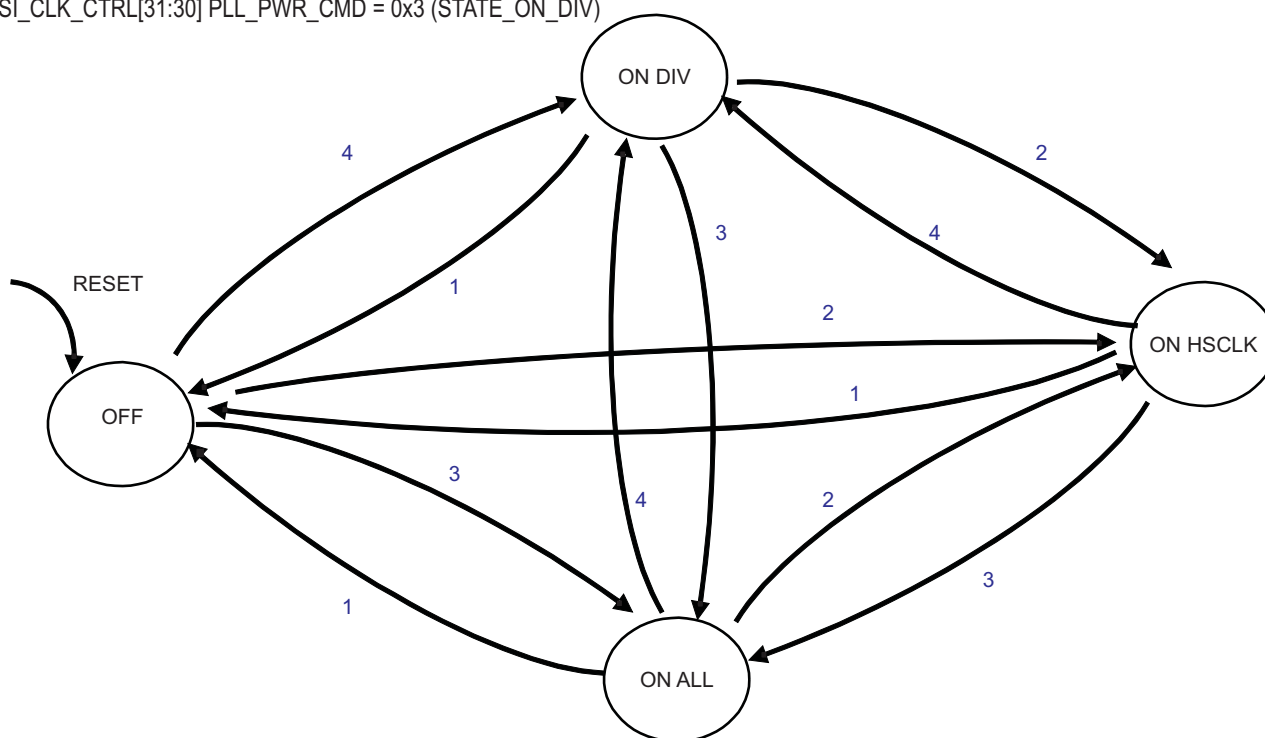

**Figure 1-95. DSI PLL Power FSM**

1 = DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD = 0x0 (STATE\_OFF)

2 = DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD = 0x1 (STATE\_ON\_HSCLK)

3 = DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD = 0x2 (STATE\_ON\_ALL)

4 = DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD = 0x3 (STATE\_ON\_DIV)

dss-170

The commands PLLPwrCmdOff, PLLPwrCmdOnAll, PLLPwrCmdOnDIV and PLLPwrCmdOnHSCLK controls the state transition of the DSI PLL control module. Software users should set the DSS.DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD field to ask for a state change. The DSS.DSI\_CLK\_CTRL[29:28] PLL\_PWR\_STATUS field gives a status on the current state of the DSI PLL controller.

**Note:** In a command requests to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL Control module).

All the DSI PLL power is controlled by the DSI protocol engine except the LDO power of the PLL and HSDIVIDER that can be controlled by the DSI PLL controller module. Indeed, the HSDIVIDER and PLL

SYSRESET signals can be forced by the DSI PLL controller module by setting respectively DSS.DSI\_PLL\_CONTROL[4] DSI\_HSDIV\_SYSRESET and DSS.DSI\_PLL\_CONTROL[3] DSI\_PLL\_SYSRESET fields. By setting these bits to 1, the SYSRESET signal is forced active (module is forced at reset state). When these bits are set to 0 (reset value), the SYSRESET signals are controlled by the DSI PLL power FSM.

#### 1.4.3.6.2.1.1 DSI-PLL HS Clock Signals

The signal DSISStopClk is provided to the DSI PLL Control module. It indicates when the DSI Protocol engine does not need to use the High Speed transfer mode (HS mode) and PLL HS output (HS\_CLK clock) can be stopped. The following conditions must also be met when DISPC\_UPDATE\_SYNC may be generated by the Display Controller, as that may also result in the PLL HS output being stopped.

When the interface is disabled (that is, DSS.DSI\_CTRL[0] IF\_EN bit set to 0), the signal DSISStopClk is asserted.

The assertion of the DSISStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is not required anymore). The get TxRequestHS deassertion, all of the following conditions are required:
  - The DSS.DSI\_CLK\_CTRL[13] DDR\_CLK\_ALWAYS\_ON bit must be reset to 0 and no HS data transfer should be on going or already scheduled
  - No virtual channel active in video mode. No virtual channel using the video mode is enabled; if the virtual channel is enabled, the mode is command mode only (that is, DSS.DSI\_VCn\_CTRL[0] VC\_EN bit set to 1 and DSS.DSI\_VCn\_CTRL[4] MODE bit set to 0)
  - No command mode requiring High speed transfer (one or more virtual channels using command mode can be active)
  - Or DSS.DSI\_CTRL[0] IF\_EN bit reset to 0 (if all previous conditions are not required)

The deassertion of the DSISStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSS.DSI\_CTRL[0] IF\_EN bit to 1):

- Clock lane TxRequestHS needs to be asserted (the DDR clock on the clock lane is required anymore).
- One video mode virtual channel active
- At least one virtual channel in command mode requiring High speed transfer
- The DSS.DSI\_CLK\_CTRL[13] DDR\_CLK\_ALWAYS\_ON bit is set to 1 by the software user (the DSS.DSI\_CTRL[0] IF\_EN bit should be reset to 0 for updating the DDR\_CLK\_ALWAYS\_ON bit value)

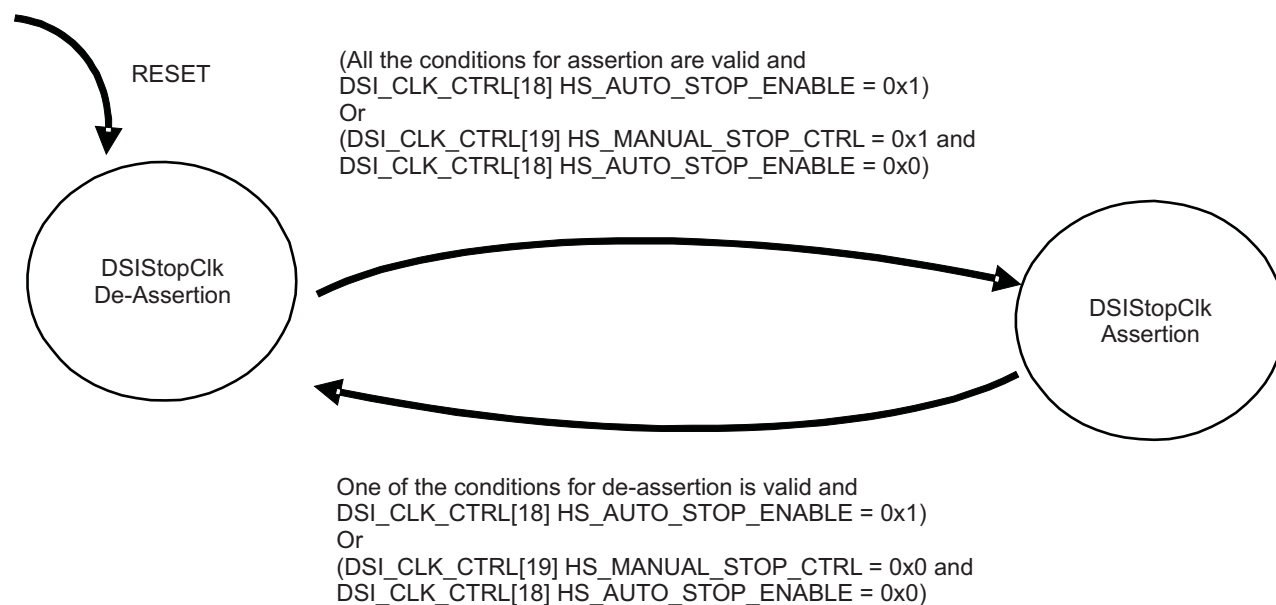

The automatic assertion/deassertion is enabled by using the DSS.DSI\_CLK\_CTRL[18] HS\_AUTO\_STOP\_ENABLE bit.

The manual mode can be used by setting/resetting the DSS.DSI\_CLK\_CTRL[19] HS\_MANUAL\_STOP\_CTRL bit to assert/deassert the DSISStopClk signal.

### 1.4.3.6.2.1.2 DSI-PLL HS Clock FSM

Figure 1-96 shows the DSI PLL HS clock FSM.

**Figure 1-96. DSI PLL HS Clock FSM**

dss-171

When DSIStopClk is used there is a latency through other modules (DSI PLL controller and DSI\_PHY) before TxByteClkHS is stopped. This latency needs to be accounted for to prevent any issue when DSIStopClk is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSS.DSI\_STOPCLK\_TIMING[7:0] DSI\_STOPCLK\_LATENCY field. This timer is programmed in number of periods of the DSI Protocol functional clock (DSI\_FCLK). At reset value, the timer is programmed with 0x80 (128) value.

#### CAUTION

The programmed value in DSS.DSI\_STOPCLK\_TIMING[7:0] DSI\_STOPCLK\_LATENCY field must be greater than:  $((3 \times L3\_ICLK \text{ period}) + (5 \times CLKIN4DDR \text{ period})) / (DSI\_FCLK \text{ period})$

### 1.4.3.7 Timers

**Note:** Among the timers described in this section, only the HS TX, LP RX and turnRequests timers generates interrupts immediately when the timer value is null. For ForceTxStopMode timer, it ends counting instantly and ForceTxStopMode is not asserted.

#### 1.4.3.7.1 Twakeup Timer

The  $T_{WakeUp}$  timer is not implemented in the DSI Protocol engine. The software must use general-purpose timer (GPTimer) to handle this. This timer is used for existing ULP mode for the active lanes (clock and/or data lanes). The sequence to exit ULP state is:

1. change the state of TxULPSExit for each lane to active
2. wait for the interrupt indicating that all lanes with TxULPSExit active have acknowledged by asserting ULPSActiveNot. This is done by reading the DSS.DSI\_COMPLEXIO\_IRQSTATUS ULPSACTIVENOT\_ALLi\_IRQ fields ( $i = 0, 1$ ).

3. start the application wake-up timer (GPTimer)
4. wait for the time-out
5. change TxUlpsClk signals to in-active state for the clock lane and/or TxRTequestEsc in-active state for the data lane(s)

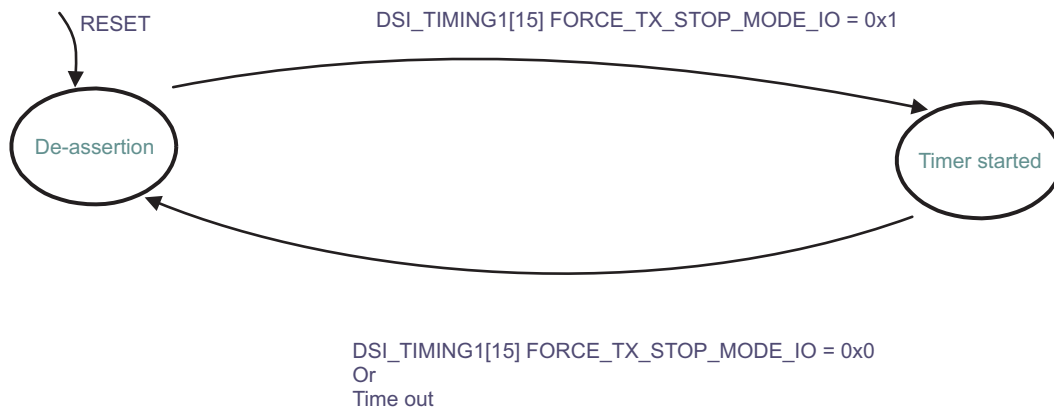

**Note:** The minimum time for the wake-up period is 1 ms.

To enter ULPS mode for clock lane, TxUlpsClk state should be change to active state. To enter ULPS mode for data lane, TxRequestEsc state should be changed to active state (TxUlpsEsc as well if it is not in active state already).

#### 1.4.3.7.2 ForceTxStopMode FSM

The signal ForceTxStopMode is used at initialization time (DSI complex I/O). [Figure 1-97](#) describes the ForceTxStopMode FSM to assert/deassert ForceTxStopMode signal.

**Figure 1-97. ForceTxStopMode FSM**

dss-172

The DSI protocol engine asserts ForceTxStopMode by setting the DSS.DSI\_TIMING1[15] FORCE\_TX\_STOP\_MODE\_IO bit to 1. Asserting the FORCE\_TX\_STOP\_MODE\_IO bit allows to initialize the lanes. The lanes are in the Stop State when ForceTxStopMode signal is high.

No data can be sent before the ForceTxStopMode signal is deasserted. The deassertion time is defined by the STOP\_STATE\_COUNTER\_IO, Stop\_State\_x4\_IO, Stop\_State\_x16\_IO field DSI\_TIMING1[15:0]. The FORCE\_TX\_STOP\_MODE\_IO bit is reset by hardware when the time is reached.

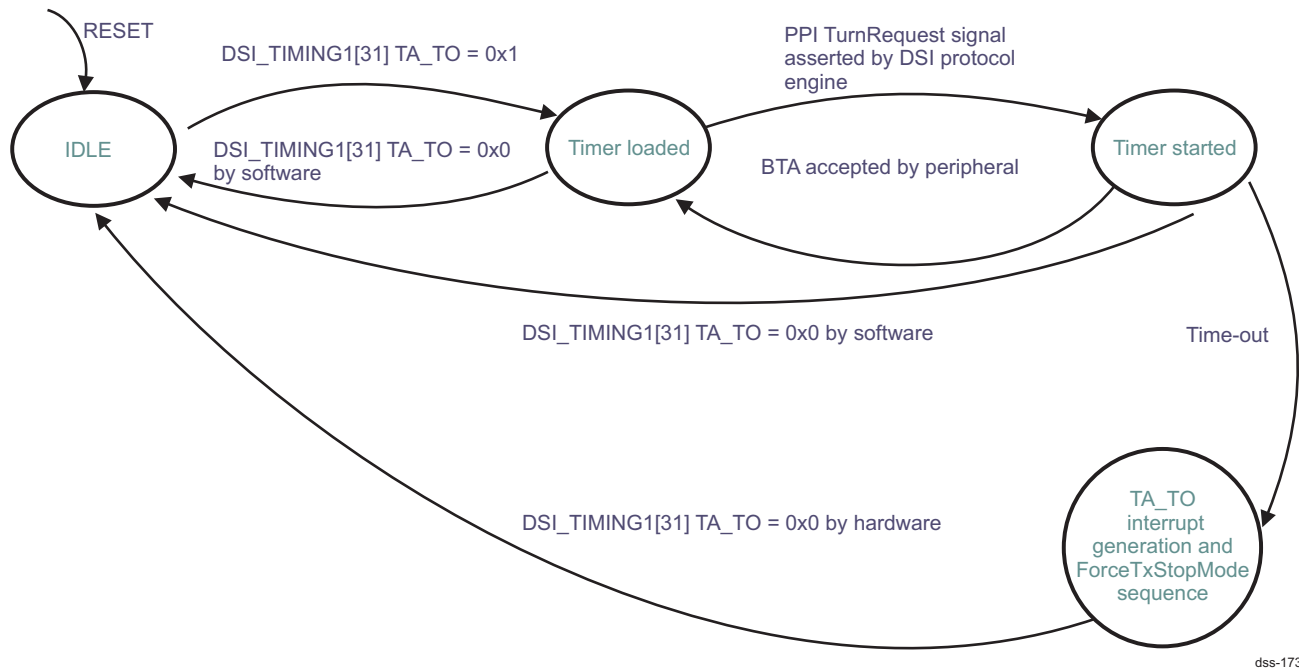

This bit can be reset by software.

The calculation of the number of DSI\_FCLK cycles assertion period is defined by:

Total period in DSI\_FCLK cycles = DSI\_TIMING1[12:0] STOP\_STATE\_COUNTER\_IO x ((DSI\_TIMING1[14] STOP\_STATE\_X16\_IO x 15) + 1) x ((DSI\_TIMING1[13] STOP\_STATE\_X4\_IO x 3) + 1)

#### 1.4.3.7.3 TurnRequest FSM

The signal TurnRequest is used to request turnaround. It is only valid for the data lane #1 since the other data lanes can not be used in the reverse direction to receive data from the DSI receiver. [Figure 1-98](#) describes the TurnRequest FSM to assert/deassert TurnRequest signal.

**Figure 1-98. TurnRequest FSM**

dss-173

The DSI protocol engine asserts TurnRequest signal during one TxClkEsc cycle when the turn-around is enabled. The DSS.DSI\_TIMING1[31] TA\_TO bit is set/reset by software to respectively enable/disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time out occurs.

The timer is loaded with the value in number of DSI\_FCLK cycles:

$$\text{DSI\_TIMING1}[28:16] \text{ TA\_TO\_COUNTER} \times ((\text{DSI\_TIMING1}[30] \text{ TA\_TO\_X16} \times 15) + 1) \times ((\text{DSI\_TIMING1}[29] \text{ TA\_TO\_X8} \times 7) + 1).$$

When the interrupt is generated, the hardware should automatically assert ForceTXStopMode in order for the DSI\_PHY to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI\_CTRL[0] IF\_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for DSS.DSI\_TIMING1[15] FORCE\_TX\_STOP\_MODE\_IO and DSS.DSI\_CTRL[0] IF\_EN bits to be reset to 0 before starting the recovery sequence.

#### 1.4.3.7.4 Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Such as the Twakeup timer, a general-purpose timer (GPTimer) should be used in case of reset of the peripheral to determine when the peripheral is ready again for operation.

#### 1.4.3.7.5 HS TX Timer

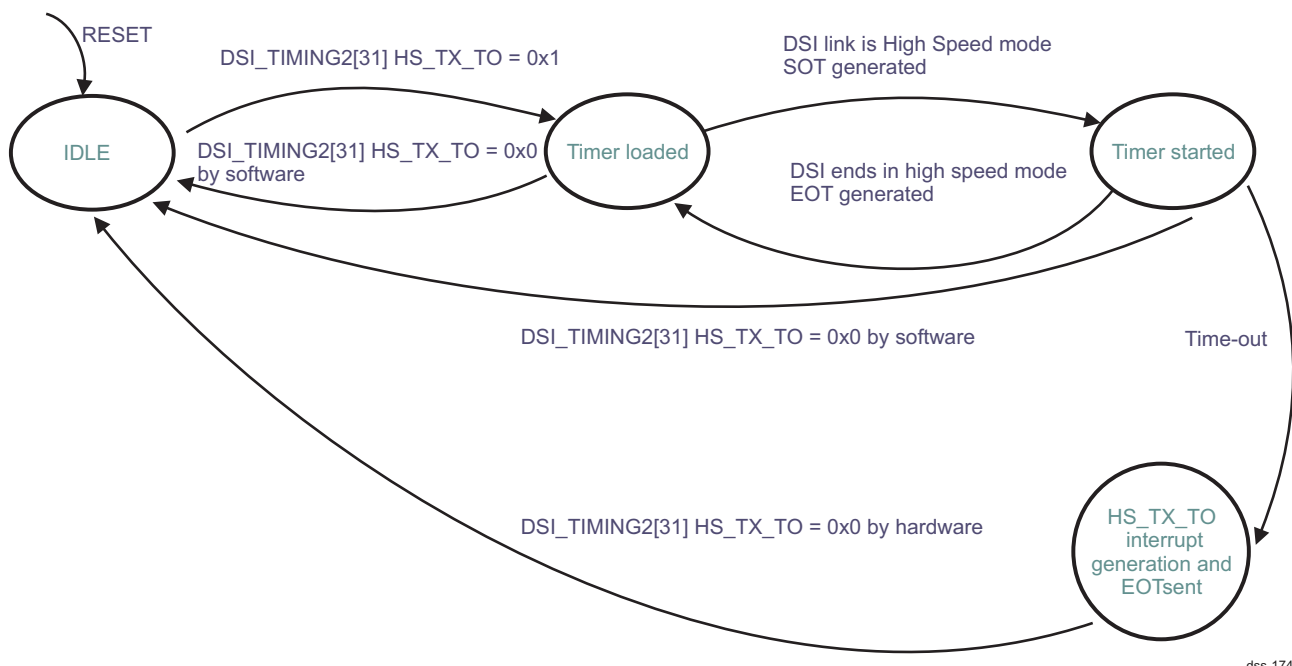

The HS TX timer is used to detect when the host has been in TX mode for too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of high speed transmission occurs. It is enabled/disabled by software through the DSS.DSI\_TIMING2[31] HS\_TX\_TO bit. The interrupt HS\_TX\_TO\_IRQ is generated when the timer expires. The DSS.DSI\_IRQSTATUS[14] HS\_TX\_TO\_IRQ bit is set to 1 when the HS TX time-out occurs.

The maximum time to be supported is 20 ms. It can be used to determine that at least once a frame in video mode, the HS mode is stopped to enter ULPS. Since the refresh rate can be up to 50 frames per second in video mode, the maximum time in HS is 20 ms.

The timer is loaded with the value in number of TxByteClkHS:

$$\text{DSI\_TIMING2}[28:16] \text{ HS\_TX\_TO\_COUNTER} \times ((\text{DSI\_TIMING2}[30] \text{ HS\_TX\_TO\_X16} \times 15) + 1) \times ((\text{DSI\_TIMING2}[29] \text{ HS\_TX\_TO\_X8} \times 7) + 1)$$

**Figure 1-99. High-Speed TX Timer FSM**

dss-174

When the time-out occurs, the hardware should send EOT request in order for the DSI complex I/O to drive LP-11 stop state. This is followed by the generation of the interrupt. The hardware will perform an internal logic reset including the TX FIFO content, but excluding the register values and then resets the DSS.DSI\_CTRL[0] IF\_EN bit.

The software should wait for the DSS.DSI\_CTRL[0] IF\_EN bit to be reset to 0 before taking any recovery action by resetting for example the peripheral if it is not responding.

#### 1.4.3.7.6 LP RX Timer

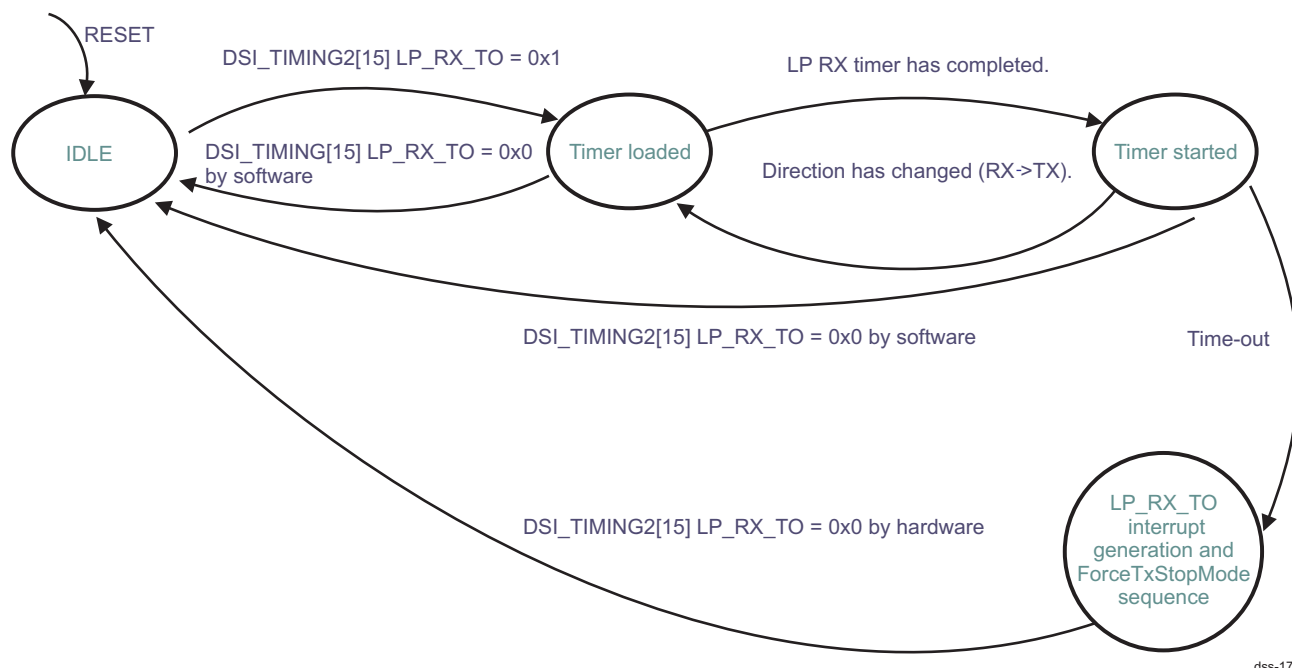

When the host is in Low power Receive mode after a bus turn-around, the LP RX timer is loaded. When the timer expires, the host requests the DSI complex I/O to drive LP-11. The interrupt LP\_RX\_TO\_IRQ is generated when the timer expires. The DSS.DSI\_IRQSTATUS[15] LP\_RX\_TO\_IRQ bit is set to 1 when the LP RX time-out occurs.

The DSS.DSI\_TIMING2[15] LP\_RX\_TO bit is set/reset by the software to respectively enable/disable the timer.

The timer is loaded with the value in number of DSI\_FCLK cycles:

$$\text{DSI\_TIMING2}[12:0] \text{ LP\_RX\_TO\_COUNTER} \times ((\text{DSI\_TIMING2}[14] \text{ LP\_RX\_TO\_X16} \times 15) + 1) \times ((\text{DSI\_TIMING2}[13] \text{ LP\_RX\_TO\_X4} \times 3) + 1)$$

**Figure 1-100. Low-Power RX Timer FSM**

dss-175

When the interrupt is generated, the hardware should automatically reset the DSS.DSI\_TIMING2[15] LP\_RX\_TO bit and then assert ForceTXStopMode in order for the DSI complex I/O to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI\_CTRL[0] IF\_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for the DSS.DSI\_TIMING1[15] FORCE\_TX\_STOP\_MODE\_IO and DSS.DSI\_CTRL[0] IF\_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when DSS.DSI\_VCn\_CTRL[0] VC\_EN is set to 1).

#### 1.4.3.8 Bus Turnaround

The bus turn-around (BTA) is not automatically sent by default after each packet sent to the display(s). It is programmable independently for each virtual channel ID. The virtual channel can be enabled when DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit is set to 1 by software. The software should ensure that, when the BTA is sent to the peripheral, there is enough time allocated for the response and the BTA from the peripheral to host. When setting the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

#### CAUTION

The BTA should not be sent when the RX FIFO is not empty. The user should take care of emptying the RX FIFO before sending BTA to the peripheral. It is to ensure that when receiving new data from peripheral, all the allocated spaces for all the virtual channels are empty.

In automatic mode, the BTA is sent automatically at the end of short or long packets when respectively the DSS.DSI\_VCn\_CTRL[2] BTA\_SHORT\_EN or the DSS.DSI\_VCn\_CTRL[3] BTA\_LONG\_EN bits are set to 1.

**Note:** If the DSS.DSI\_VCn\_CTRL[2] BTA\_SHORT\_EN bit is enabled, the user can still set the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit is reset by hardware.

If the DSS.DSI\_VCn\_CTRL[3] BTA\_LONG\_EN bit is enabled, the user can still set the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit is reset by hardware.

If the DSS.DSI\_VCn\_CTRL[2] BTA\_SHORT\_EN and DSS.DSI\_VCn\_CTRL[3] BTA\_LONG\_EN bits are both enabled, the user can still set the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit to send a BTA. Only one BTA is sent and the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit is reset by hardware.

As explained previously, two modes can be used for each virtual channel ID:

- **Automatic:** After each packet, a bus turn-around is sent. To determine the size of the long packet, the protocol engine on the host side should read the word count defined in the header (in DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register) and use it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. Then the bus turn-around is sent to the peripheral. The word count is also used to determine how many bytes should be transferred from the 32-bit writes access to the payload register (DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register).
- **Manual:** In case of data transfer using the L4 interconnect port, while all data have been provided to the DSI protocol engine, the user can select bus turn-around for the last packet provided to the L4 interconnect port only by setting the bus turn-around enable bit (DSS.DSI\_VCn\_CTRL[6] BTA\_EN) or for last packets and following ones by setting the automatic mode; in case of data transfer using the video port, the bus turnaround enable bit (DSS.DSI\_VCn\_CTRL[6] BTA\_EN) can be selected at any time during the transfer of the packet. In case of video mode packets (data and synchronization events) the user can not determine when the BTA is sent relatively the video mode packets, so it is highly recommended to use manual BTA mode only for packets generated in command mode but it is possible to use BTA when for a virtual channel in video mode. In case of data provided on the video port, an interrupt for end of packet transfer (PACKET\_SENT\_IRQ) is provided to the user to know when the packet has been completely sent by the DSI complex I/O. The PACKET\_SENT\_IRQ can be monitored in DSI\_VCn\_IRQSTATUS[2] PACKET\_SENT\_IRQ status bit. The user can request BTA even if the space allocated in the TX FIFO for the corresponding VC is empty. It can be sent later on even if there was no packet sent before BTA request. The DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit should be reset by hardware if the BTA request has been sent even if the automatic mode for this specific type of packets is enabled.

The bus turn-around is supported for video mode packets and for command mode packets. It is not possible to send BTA during the blanking periods of the video mode when HS blanking packets should be sent - that is, when one of the following bits is set to 1: DSS.DSI\_CTRL[20] BLANKING\_MODE, DSS.DSI\_CTRL[21] HFP\_BLANKING\_MODE, DSS.DSI\_CTRL[22] HBP\_BLANKING\_MODE or DSS.DSI\_CTRL[23] HSA\_BLANKING\_MODE. So in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

#### TA Timer

When TurnRequest signal is asserted (always only for data lane #1), the TA\_TO timer is started. If the direction signal is no changed according to the turn-around request, the TA\_TO interrupt is generated. When the Direction signal is in output mode, any data on the input data bus should be ignored since the DSI is in transmission mode (data and triggers should be ignored). Refer [Section 1.4.3.7.3](#) to for more details on TA\_TO timer.

### 1.4.3.9 PHY Triggers

Three triggers are used by the DSI protocol engine:

- reset from host to display
- tearing effect from display to host
- acknowledge

These triggers are supported only for data lane #1. The reset trigger is associated with the signal TxTriggerEsc1[3]. The tearing effect trigger is associated with the signal RxTriggerEsc1[2]. The acknowledge trigger is associated with the signal RxTriggerEsc1[1].

---

**Note:** The TX signals - TxTriggerEsc1[2], TxTriggerEsc1[1], and TxTriggerEsc1[0] - and the RX signals - RxTriggerEsc1[3], and RxTriggerEsc1[0] - are not used by DSI protocol engine.

---

#### 1.4.3.9.1 Reset

The DSI protocol engine can use one of the triggers of the DSI\_PHY to send a reset to the display. The DSS.DSI\_CTRL[5] TRIGGER\_RESET bit is set to 1 to send the trigger reset. When the software requires the trigger reset to be sent to the peripheral, the DSI protocol engine should reset its own logic but not the registers. The software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already taken into account for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is only valid if there is virtual channel using the video mode and if it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on VP after the current frame are ignored.

To select the reset mode, software users must program the DSS.DSI\_CTRL[14] TRIGGER\_RESET\_MODE.

#### CAUTION

For both reset modes, the hardware is responsible for flushing the FIFOs, synchronization buffers and line buffers before resetting the DSS.DSI\_CTRL[0] IF\_EN bit.

#### 1.4.3.9.2 Tearing Effect

The tearing effect on the display is avoided by having synchronization information from the display. It is used only in command mode. In case of video mode, it is not functional. It is the user responsibility to select command mode for the virtual channel using the tearing effect feature.

The software is responsible for setting and sending the appropriate sequence to receive the tearing effect trigger from the peripheral. When receiving the tearing effect trigger, the DSI protocol engine should generate the TE\_TRIGGER\_IRQ interrupt with TE event if the interrupt is enabled. To enable the interrupt, set to 1 the DSS.DSI\_IRQENABLE[16] TE\_TRIGGER\_IRQ\_EN bit. The DSS.DSI\_IRQSTATUS[16] TE\_TRIGGER\_IRQ status bit indicates if the interrupt event has been generated.

One or multiple virtual channels can be synchronized using the same tearing effect trigger. The DSS.DSI\_VCn\_TE[16] TE\_EN bit should be set to indicate that the hardware should use the following TE trigger to start the transfer of the data from the related virtual channel. This bit is reset when all the data have been sent to the peripheral. The DSS.DSI\_VCn\_TE[17] TE\_START bit should be used when the automatic mode enabled by setting the DSS.DSI\_VCn\_TE[16] TE\_EN bit is not used. It allows the user to start the transfer manually based on application events or based on the TE trigger interrupt (TE\_TRIGGER\_IRQ).

The number of bytes to be transferred is defined by using the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field. The TE\_SIZE field is decremented for each payload byte (it does not include Check-sum) sent on the DSI link. The register content should not be modified by software during a transfer. The DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field should be set first to indicate that the following accesses to DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register should be used for tearing effect transfer.

The data can be provided from two sources (selection by setting the DSS.DSI\_VCn\_CTRL[1] SOURCE bit):

- L4 interconnect port using DMA request: The DMA request DSI\_DMA\_REQ<sub>i</sub> (i=0 to 3) to should be asserted only when TE trigger is received or when the DSS.DSI\_VCn\_TE[17] TE\_START bit is set by user and should not be asserted anymore when all the bytes defined in DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field have been sent on the DSI link. The virtual channel is associated with a DMA request (from DSI\_DMA\_REQ0 to DSI\_DMA\_REQ3) by programming the number in the DSS.DSI\_VCn\_CTRL[23:21] DMA\_TX\_REQ\_NB field. The DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register is used to provide the number of bytes defined by the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field (the check-sum value is not provided in the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register). The size of the header is not taken into account in the number of bytes to transfer. The DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER register is not used.
- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. In case there is no line buffer instantiated (that is, DSS.DSI\_CTRL[13:12] LINE\_BUFFER field set to 0), it is not possible to use the video port to provide data. The line buffer should be filled up according to the word count defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register header. The value should be written before the TE trigger event is received or before the DSS.DSI\_VCn\_TE[17] TE\_START bit is set to 1 by software. In case the total number of bytes defined by the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field is not a multiple of the word count defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register, all the packets have the same size defined by the WC of the header except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Since the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field is modified after each packet transfer, the size of the last packet is equal to the value of DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field just before the last transfer (the header and the payload check-sum sizes are not included in DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field).

When the transfer is completed, the value of the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE field is equal to 0. The software is responsible to ensure that the pending data in the TX FIFO for the corresponding virtual channel using TE are related to TE transfer. Any data in the TX FIFO that should be sent before reception of TE trigger should be sent before TE. This is done by not enabling TE trigger until all data for the corresponding VC have been sent to the peripheral. The software can check that the space allocated for the virtual channel in the TX FIFO is empty by reading the DSS.DSI\_VCn\_CTRL[5] TX\_FIFO\_NOT\_EMPTY status bit.

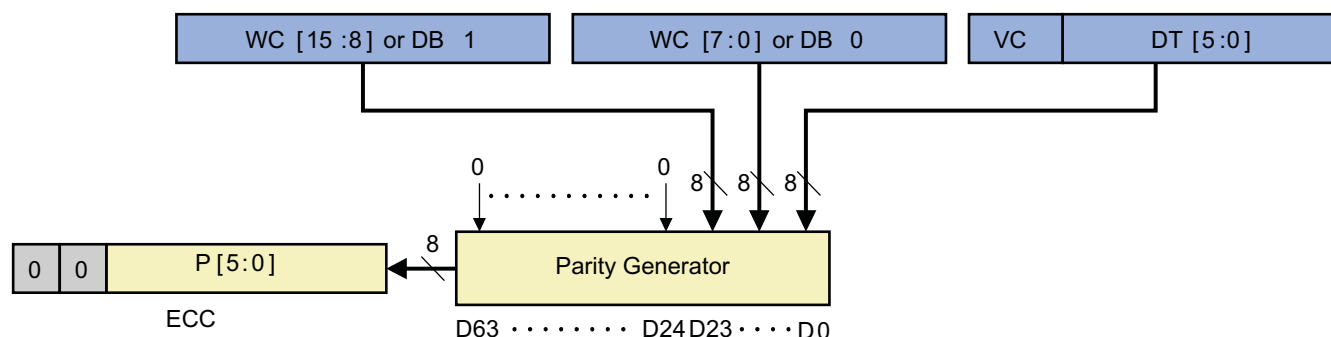

#### 1.4.3.9.3 Acknowledge

The corresponding Acknowledge interrupt (ACK\_TRIGGER\_IRQ) should be generated upon reception of the acknowledge trigger. To enable the acknowledge interrupt, set the DSS.DSI\_IRQENABLE[17] ACK\_TRIGGER\_IRQ\_EN bit to 1. When the interrupt is generated, the DSS.DSI\_IRQSTATUS[17] ACK\_TRIGGER\_IRQ status bit is set to 1.

#### 1.4.3.10 ECC Generation

Note that the DSI protocol uses a four-byte packet header. Since ECC generation requires a fixed word length of 64-bits, the packet headers should be padded with additional bits to form a full eight-byte value for ECC generation and checking. The packet header less the ECC byte should occupy bits D[23:0] and the pad bits should occupy bits D[63:24]. All padding bits should be zero for the purpose of generating the ECC byte. ECC can be generated using a parallel approach as illustrated in [Figure 1-101](#).

**Figure 1-101. 64-Bit ECC Generation on TX Side**

dss-176

The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the virtual channels:

- The DSS.DSI\_CTRL[2] ECC\_RX\_EN bit enables/disables the ECC generation in the receive direction.
- The DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit enables/disables the ECC generation in the transmit direction

### 1.4.3.11 Checksum Generation for Long Packet Payloads

Long packets are comprised of a packet header protected by an ECC byte and a payload of 0 to  $2^{16} - 1$  bytes. To detect the errors during the transmission of Long packets, a checksum is calculated over the payload portion of the data packet. Note that, for the special case of a zero-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can only indicate the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations since the peripheral has no way for reporting errors to the host processor. Checksum generation and transmission is mandatory for host processors sending Long packets to peripherals. It is optional for peripherals transmitting Long packets to the host processor. However, the format of Long packets is fixed; the peripherals that do not support checksum generation should transmit two bytes having value 0x0000 in place of the checksum bytes when sending Long packets to the host processor. The host processor should disable checksum checking for received Long packets from peripherals that do not support checksum generation.

The checksum should be realized as a 16-bit CRC with a generator polynomial of  $x^{16} + x^{12} + x^5 + x^0$ . The LS byte is sent first, followed by the MS byte. Note that within the byte, the LS bit is sent first.

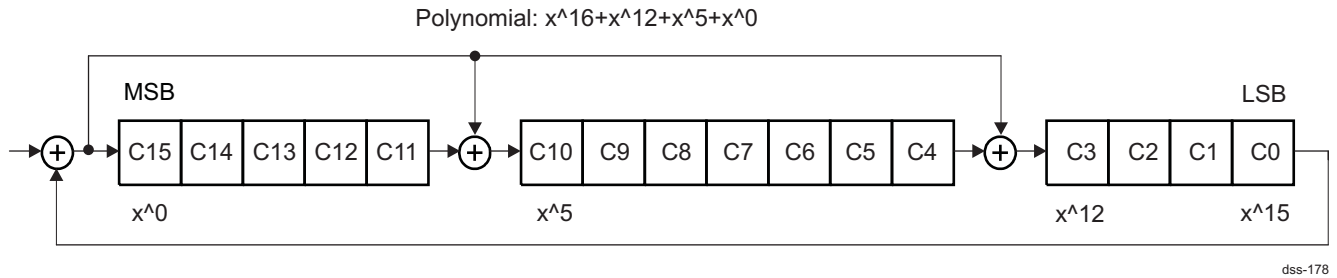

**Figure 1-102. Checksum Transmission**

dss-177

The CRC implementation is presented in [Figure 1-103](#). The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the packet header then enters as a bitwise data stream from the left, LS bit first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the checksums MSB and C0 the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

**Figure 1-103. 16 Bit CRC Generation Using a Shift Register**

The check-sum generation/check can be enabled and disabled by software. It is defined by a common bit for all the virtual channels:

- The DSS.DSI\_CTRL[1] CS\_RX\_EN bit enables/disables the check-sum generation in the receive direction.
- The DSS.DSI\_VCh\_CTRL[7] CS\_TX\_EN bit enables/disables the check-sum generation in the transmit direction

#### 1.4.4 DSI PLL Controller Functionalities

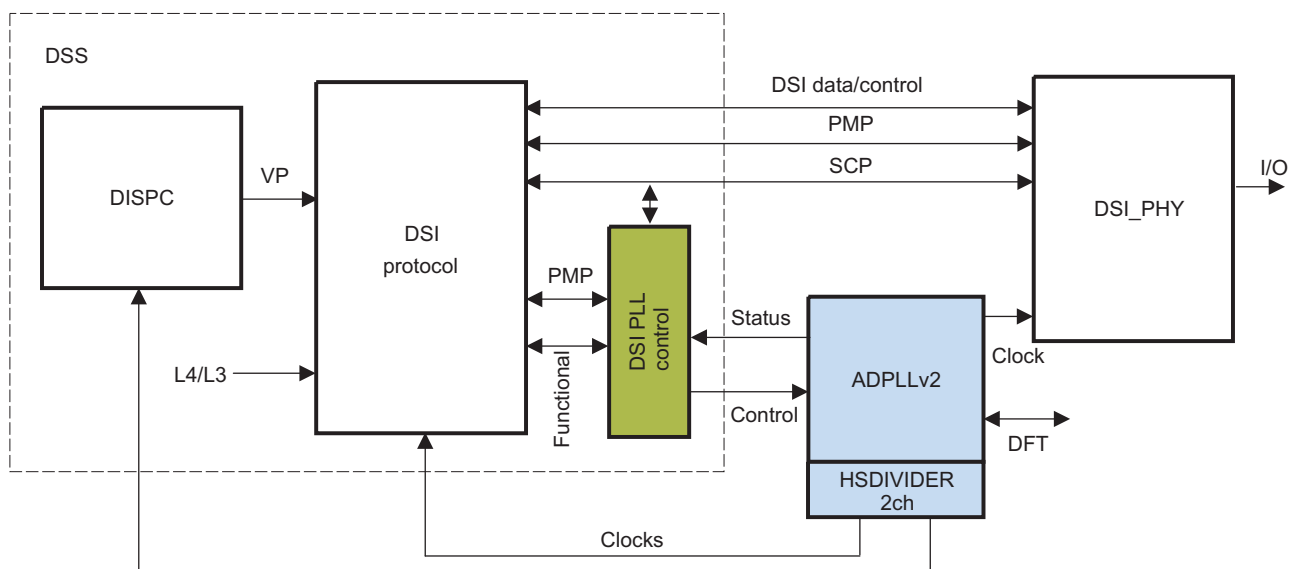

This section describes functionality associated with the DSI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

##### 1.4.4.1 DSI PLL Controller Overview

The DSI PLL controller module forms part of the Display Sub-system. Nevertheless, it uses the SCP (Serial Configuration Port) and PMP (Power Management Port) ports as the primary interfaces to the DSI protocol engine. The SCP interface is used to set the configuration of the DPLL and HSDIVIDER modules, primarily the various counter values. The PMP port is used to control the power state of the DPLL and HSDIVIDER modules. [Figure 1-104](#) provides an overview of the DSI PLL controller module inside the Display Subsystem.

The DSI PLL is also used to generate the 74.25-MHz frequency used for HDTV applications.

**Figure 1-104. DSI PLL Controller Overview**

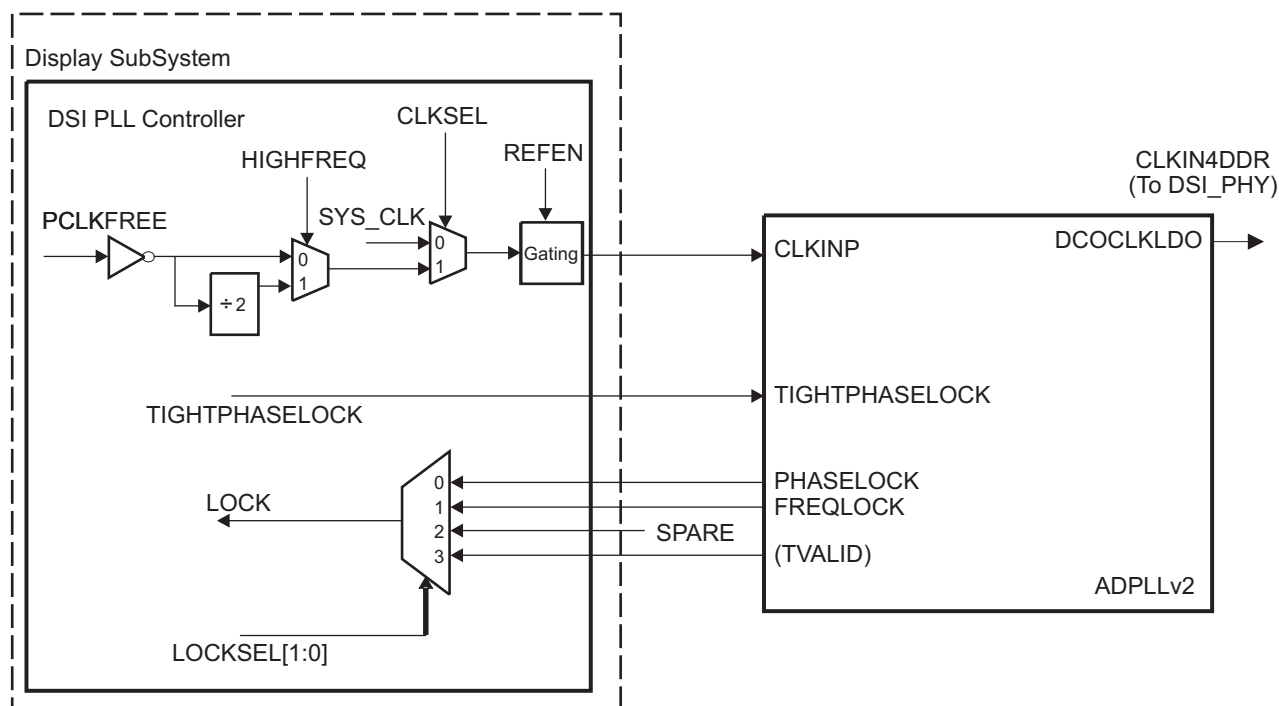

**Note:** The DSI PLL controller module does not have an interface to L4 interconnect. The programmable features are managed by registers mapped into the DSI protocol engine.

#### 1.4.4.2 DSI PLL Controller Architecture

The DSI PLL is an ADPLLv2 module. The pixel clock (PCLK) frequency range is 2 to 65 MHz. This may be divided by 2. This is performed by setting the DSS.DSI\_PLL\_CONFIGURATION2[12] DSI\_PLL\_HIGHFREQ bit to 1.

Figure 1-105 shows the internal DSI PLL reference diagram.

**Figure 1-105. DSI PLL Reference Diagram**

Note: PCLK is inverted as the falling edge is the reference edge and ADPLLv2 uses positive edge as reference (F/F should be positive edge clock also)

dss-180

The DSI PLL clock output (DSI\_PLL\_HSCLK) corresponds to the CLKIN4DDR clock of the DSI complex I/O module.

The DSI PLL reference clock is the DSI\_PLL\_REFCLK clock. Depending on the setting in DSS.DSI\_PLL\_CONFIGURATION2[11] DSI\_PLL\_CLKSEL bit, the reference clock can be either the DSS2\_ALWON\_FCLK provided by the PRCM or the PCLKFREE provided by the DISPC module.

**1.4.4.3** The DSI PLL configuration signals operate according to Table 1-32. Table 1-32 indicates the operation when the PLL is not locked.

**Table 1-32. DSI PLL Operation Modes When Not Locked**

DSI PLL Operation Mode	Stop mode Low power <sup>(1)</sup>	Stop mode Fast Relock <sup>(1)</sup>	Idle bypass
Mode Description	Output clocks stopped Lowest power standby	Output clocks stopped Fastest start-up time	Selects when PLL and HSDIVIDER bypass clocks are used
DSS.DSS_PLL_CONFIGURATION2[0] DSI_PLL_IDLE	0	0	1
DSS.DSS_PLL_CONFIGURATION2[6] DSI_PLL_LOWCURRSTBY	1	0	1
DSS.DSS_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE	1	1	X

<sup>(1)</sup> Recommended

When locked, the PLL output frequency is: Input frequency x M /(N+1)/HIGHFREQ where:

- M multiplier is programmed in DSS.DSI\_PLL\_CONFIGURATION1[18:8] DSI\_PLL\_REGM field.
- N divider is programmed in DSS.DSI\_PLL\_CONFIGURATION1[7:1] DSI\_PLL\_REGN field.
- HIGHFREQ divider by 2 is enabled by setting the DSS.DSI\_PLL\_CONFIGURATION2[12] DSI\_PLL\_HIGHFREQ bit to 1.

#### 1.4.4.4 DSI PLL Controller Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register space using SCP port. This includes all the configuration signals and the returning status signals.

#### CAUTION

All writes must be 32-bit operations as the SCP always transfers 32 bits. Any 16-bit or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations may optionally be updated in synchronism with the Display Controller (DISPC) and DSI protocol engine. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must have been written before this signal is asserted. Refer to [Section 1.4.3.5.1](#) for more details.

#### 1.4.4.5 Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI\_PLL\_STATUS[1] DSI\_PLL\_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI\_PLL\_STATUS[2] DSI\_PLL\_RECAL status bit informs if the PLL needs to be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- The PLL\_LOCK\_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSS.DSI\_IRQSTATUS[7] PLL\_LOCK\_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL\_UNLOCK\_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSS.DSI\_IRQSTATUS[8] PLL\_UNLOCK\_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL\_RECAL\_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSS.DSI\_IRQSTATUS[9] PLL\_RECAL\_IRQ bit. Set this bit to 1 to clear the status bit.

## 1.4.5 DSI Complex I/O Functionalities

This section describes functionality associated with the DSI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

### 1.4.5.1 DSI Complex I/O Overview

The DSI complex I/O or DSI\_PHY is a MIPI DSI\_PHY compliant transceiver. It is used in the DSI interface between a mobile phone application device and a display module.

DSI\_PHY is a complex I/O with 3 unidirectional (HS) Lane Modules. This includes 2 data lane modules and 1 clock lane module. Each lane module has 2 data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using point to point interconnect.

Lane modules support High speed burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes maybe used for Low Power Data Transmission, among other things. DSI\_PHY lane modules correspond to CIL-MFDA and CIL-MCNN lane type defined by DSI\_PHY specification.

The maximum data rate supported in High Speed Mode is 800Mbps per data lane. The lane module function and position is configurable, that is, any lane module can be chosen as clock lane module, and DX/DY data pad for each lane module can be configured as either DP or DN pins defined by DSI\_PHY spec.

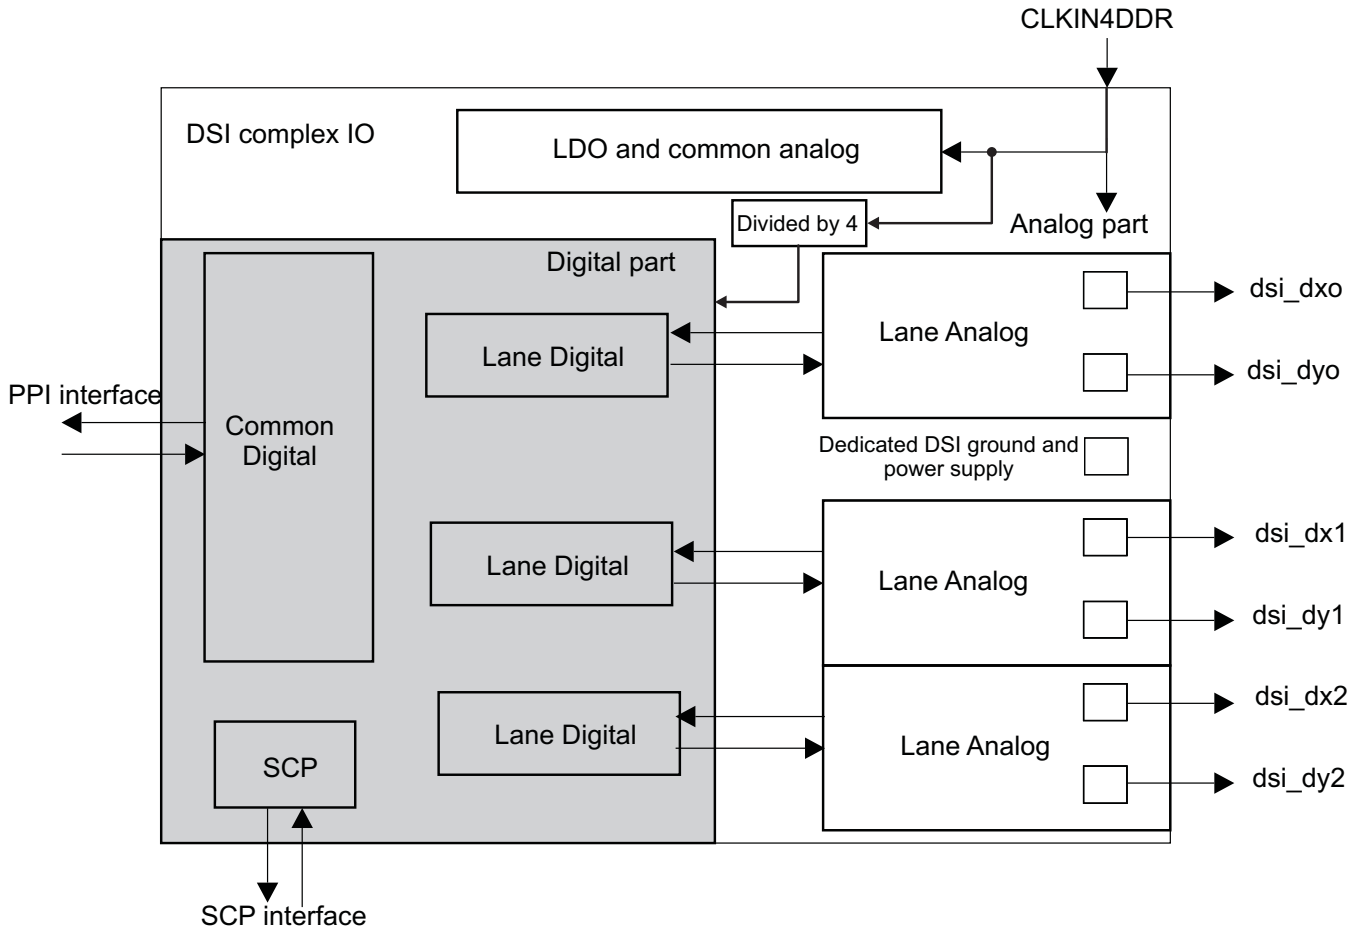

DSI\_PHY interacts with the higher layers of the DSI link through the PHY-Protocol Interface (PPI). DSI\_PHY does not include a PLL; a high frequency clock input is expected in HS mode (CLKIN4DDR). DSI\_PHY supports also Serial Configuration Protocol (SCP) to set various configuration and control registers. The DSI\_PHY supports GPIO operation on each of the six data pins.

### 1.4.5.2 DSI Complex I/O Architecture

[Figure 1-106](#) shows the top-level block diagram of DSI\_PHY. It has 3 lane module functions, and some common analog and digital functions. Each lane module has an analog and a digital part. The digital lane circuitry implements the protocol interface of MIPI DSI\_PHY. It interacts with the DSI protocol engine.

Figure 1-106. DSI Complex I/O Architecture

dss-189

The internal input & output interfaces of DSI\_PHY are compliant with PHY-Protocol Interface (PPI) description of the MIPI DSI\_PHY specification annex. The explanation of DSI\_PHY interface and PPI protocol is in the MIPI DSI\_PHY specification document.

The lane module analog circuit converts the digital levels to the LP and HS level signals for the link. It also converts the analog state of the link into digital levels.

For High Speed signals, the lane module analog also does the last stage untiming of HS data to obtain optimum quadrature with the HS clock.

DSI\_PHY has an internal LDO to generate 1.2V supply. This LDO requires an off-chip decoupling capacitor and hence a dedicated pin. DSI\_PHY expects a high frequency clock input in HS mode.

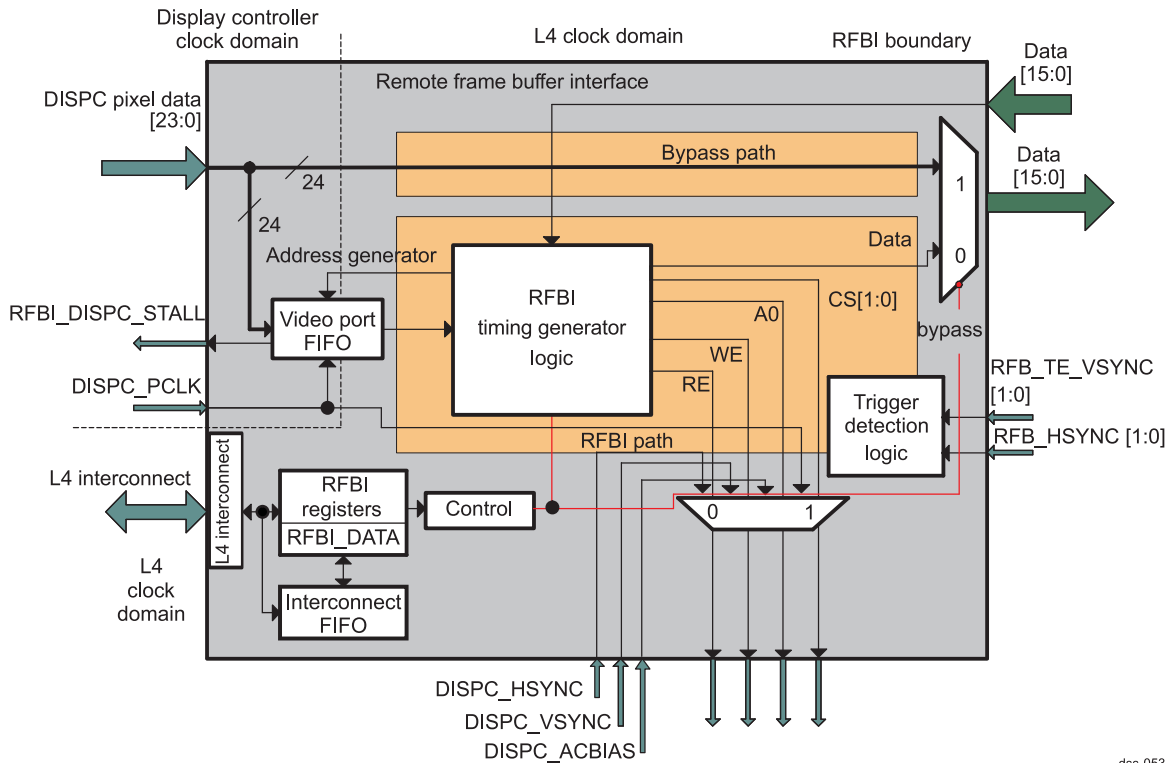

The clock input is required to have four times the frequency of the DDR clock, that is, twice the HS data rate. GPIO functions are supported on each dsi\_dxi and dsi\_dyi.

#### 1.4.6 RFBI Functionalities

The RFBI module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFBI module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment.

Figure 1-107 shows an overview of the RFBI architecture.

**Figure 1-107. RFBI Architecture Overview**

dss-053

#### 1.4.6.1 RFBI FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFBI and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. [Section 1.4.6.4, Output Parallel Modes](#), shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

#### 1.4.6.2 RFBI Interconnect FIFO

The interconnect FIFO receives the data from RFBI\_DATA write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (i.e 24 words of RFBI\_DATA).

#### 1.4.6.3 Input Pixel Formats

The supported pixel formats in the RFBI module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

#### 1.4.6.4 Output Parallel Modes

The RFBI output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format ( $i = 0$  or  $1$ ) (see also [Table 1-33](#)):

- The DSS.RFBI\_CONFIG $i$ [10:9] CYCLEFORMAT field is set to 0x3 (three cycles for two pixels).
- The DSS.RFBI\_DATA\_CYCLE1\_ $i$  register is set to 0x00000010 (16 bits from pixel 1 for the first cycle).
- The DSS.RFBI\_DATA\_CYCLE2\_ $i$  register is set to 0x00080808 (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.RFBI\_DATA\_CYCLE3\_ $i$  register is set to 0x00100000 (16 bits from pixel 2 for the third cycle).

**Table 1-33. 16-Bit Interface Configuration/24-Bit Mode**

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[15]	R0[7]	B0[7]	G1[7]
Data[14]	R0[6]	B0[6]	G1[6]
Data[13]	R0[5]	B0[5]	G1[5]
Data[12]	R0[4]	B0[4]	G1[4]
Data[11]	R0[3]	B0[3]	G1[3]
Data[10]	R0[2]	B0[2]	G1[2]
Data[9]	R0[1]	B0[1]	G1[1]
Data[8]	R0[0]	B0[0]	G1[0]
Data[7]	G0[7]	R1[7]	B1[7]
Data[6]	G0[6]	R1[6]	B1[6]
Data[5]	G0[5]	R1[5]	B1[5]
Data[4]	G0[4]	R1[4]	B1[4]
Data[3]	G0[3]	R1[3]	B1[3]
Data[2]	G0[2]	R1[2]	B1[2]
Data[1]	G0[1]	R1[1]	B1[1]
Data[0]	G0[0]	R1[0]	B1[0]

#### 1.4.6.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

#### 1.4.6.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

#### 1.4.6.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.RFBI\_CMD register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

### 1.4.6.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI\_A0 signal), WE (RFBI\_WE signal), RE (RFBI\_RE signal), and CSx (RFBI\_CSx signal, with x = 0, 1) is programmable.

Table 1-34 describes the read/write function.

**Table 1-34. Read/Write Function Description**

A0 (RFBI_A0)	WE (RFBI_WE)	RE (RFBI_RE)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI\_Cs cycle time, as defined in Table 1-35, is required to keep the RFBI\_CSx signal asserted between write transfers of multiple pixels.

Table 1-35 indicates the minimum cycle time for RFBI\_CSx, depending on the source of pixels (display controller or L4 Interconnect slave port) and the cycle format (1 pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

**Table 1-35. Minimum Cycle Time for CSx/WE Always Asserted**

RFBI Performance	RFBI_CONFIGi[10:9] CYCLEFORMAT	RFBI_CONFIGi[8:7] L4FORMAT	Minimum Cycle Time (in Number of L4 Cycles)
L4 interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	2 pixels/3 cycles	1 pixel	6
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
	2 pixels/3 cycles	2 pixels	6
Display Controller	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixels/3 cycles	N/A	6

### 1.4.7 Video Encoder Functionalities

The input formats supported by the encoders are 24-bit 4:4:4 RGB. The encoder output is the DAC (for more information, see Section 1.2, *Display Subsystem Environment*). In the display subsystem, the input format from the display controller is always 24-bit RGB. The RGB-to-YCbCr color space converter converts the 24-bit RGB pixel data to 24-bit YCbCr data.

The remaining Cb and Cr color components enter the 2-to-1 chrominance decimation, which reduces by half the chrominance bandwidth and the amount of chrominance data. After the data manager, the encoder processes in 4:2:2 data path up to the 2x interpolation. A luma delay synchronizes luma to chrominance data.

Figure 1-108 shows an overview of the video encoder architecture.

### 1.4.7.2 Luma Stage

The luma stage includes a luma pipeline delay, luma shaping, 2x interpolation filter, and luma variable delay. The luma pipeline delay block is used to match luma path length to chroma path length. In the luma gain shaper, a programmable gain is first applied to the luminance data output. The luminance gain is defined by the DSS.VENC\_GAIN\_Y register. Horizontal sync, vertical sync, and setup insertion are then performed.

Black level and blank level are programmable through the DSS.VENC\_BLACK\_LEVEL and DSS.VENC\_BLANK\_LEVEL registers. All the transition edges of the luminance signal, such as sync edges and active video edges, are properly shaped and filtered to keep the bandwidth within the standards.

After all required components of the luminance signal are added, the resulting signal is low-passed and interpolated to 2x-pixel rate. This 2x interpolation simplifies the external analog reconstruction filter design and improves the signal-to-noise ratio.

### 1.4.7.3 Chroma Stage

The chroma stage includes a low-pass filter, first-stage 2x interpolation, chroma gain shaper, and second-stage 2x interpolation. A pair of programmable gains adjusts the time-multiplexed U/V signal. The gains for U and V are independently controlled by the DSS.VENC\_GAIN\_U and DSS.VENC\_GAIN\_V register bits.

### 1.4.7.4 Subcarrier and Burst Generation

The encoder uses a 32-bit subcarrier increment to synthesize the subcarrier. The value of the subcarrier increments required to generate the desired subcarrier frequency for NTSC and PAL format is found by:

$$S\_CARR = \text{ROUND} ([F_{sc}/F_{clkenc}] \times 2^{32})$$

where:

$F_{sc}$  = Frequency of the subcarrier

$F_{clkenc}$  = Frequency of the internal video encoder

The DSS.VENC\_S\_CARR register controls the subcarrier frequency. The DSS.VENC\_C\_PHASE register controls the phase of the subcarrier. The phase of the color subcarrier is reset to DSS.VENC\_C\_PHASE. [Table 1-37](#) presents the VENC\_S\_CARR register values depending the standard and pixel type used.

**Table 1-37. VENC\_S\_CARR Register Recommended Values**

Standard	Pixel Type	Subcarrier Frequency (Fsc) (MHz)	Fclkenc (MHz)	VENC_S_CARR register value (hexa)
NTSC-M, J	ITU-R601	3.579545	27	0x21F07C1F
PAL-M	ITU-R601	3.5756083125	27	0x21E6EFE3
PAL-B, D, G, H, I, N	ITU-R601	4.43361875	27	0x2A098ACB
PAL-Nc	ITU-R601	3.58205625	27	0x21E6EFE3
NTSC-M, J	Square pixel	3.579545	24.5454	0x25555555
PAL-M	Square pixel	3.579561149	24.5454	0x1F15C01E
PAL-B, D, G, H, I, N	Square pixel	4.43361875	29.50	0x26798C0C
PAL-Nc	Square pixel	3.58205625	29.50	0x1F15C01E

### CAUTION

In square pixel mode, an external clock generator is needed to provide sampling frequencies (49.09 MHz for NTSC square pixel or 59 MHz for PAL square pixel).

The color subcarrier reset has four modes:

- No reset
- Reset every two lines
- Reset every two fields
- Reset every eight fields

The DSS.VENC\_C\_PHASE register can be used to adjust the SCH (subcarrier to horizontal sync phase). The DSS.VENC\_BSTAMP\_WSS\_DATA[6:0] BSTAP field sets the amplitude of the color burst. The DSS.VENC\_M\_CONTROL[1] PAL bit enables phase alternation line encoding.

A phase switching subcarrier is generated to encode the chrominance signal when the DSS.VENC\_M\_CONTROL[1] PAL bit is set to 1. Otherwise, a normal subcarrier is generated. Phase alternation line refers to the encoding scheme in which the subcarrier alternates between two phases every scan line. Two possible alternation sequences are possible, and the DSS.VENC\_M\_CONTROL[5] PALPHS bit selects one of these sequences.

#### 1.4.7.5 Closed Caption Encoding

The encoder can be programmed to encode closed-caption data and extended data in the selected line. The closed-caption data are sent to the encoder through the L4 interconnect. The data stream consists of 7-bit US-ASCII code and 1 odd-parity bit (see [Table 1-38](#)).

**Table 1-38. Closed-Caption Data Format**

MSB						LSB	
Odd parity	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

The standard service encodes closed caption in both fields; the extended service encodes closed caption in even fields. When set to 1, the DSS.VENC\_L21\_WC\_CTL L21EN[0] bit enables closed-caption encoding in odd fields. When set to 1, the DSS.VENC\_L21\_WC\_CTL L21EN[1] bit enables closed-caption encoding in even fields.

There is a 4-line offset between the value programmed in the DSS.VENC\_LN\_SEL[4:0] SLINE field and the scan line where closed caption is to be encoded. Program the value 0x11 to activate the closed caption on line 21. The DSS.VENC\_LN\_SEL[25:16] LN21\_RUNIN field should be kept at reset value (0x10B). Four closed-caption data registers contain the data to be encoded. The DSS.VENC\_LINE21[7:0] L21O and DSS.VENC\_LINE21[15:8] L21O fields contain the first and the second bytes of closed-caption data to be encoded in the odd field. The DSS.VENC\_LINE21[23:16] L21E and DSS.VENC\_LINE21[31:24] L21E fields contain the first and the second bytes of data to be encoded in the even field.

Immediately after the closed-caption data is written to the registers, in either the odd field or even field, the corresponding closed-caption status bit (DSS.VENC\_STATUS[4] CCE or DSS.VENC\_STATUS[3] CCO) is reset to 0 to indicate that the closed-caption data is available in the closed-caption data registers and yet to be encoded.

Immediately after the closed-caption data is encoded, the DSS.VENC\_STATUS[4] CCE bit or the DSS.VENC\_STATUS[3] CCO bit is set to 1 to indicate that the closed-caption data has been encoded and is ready to accept new data. As seen in [Figure 1-109](#), a null character is automatically inserted if the closed-caption data is not written to the closed-caption data registers in time for encoding.

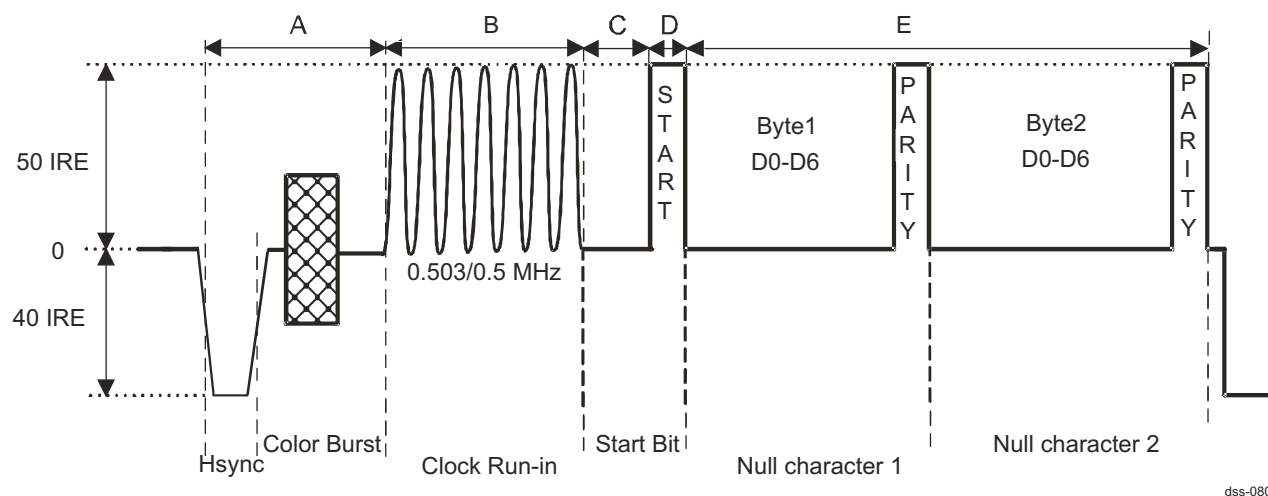

The running clock frequency is controlled by the DSS.VENC\_CC\_CARR\_WSS\_CARR[15:0] FCC field which should be kept at reset value (0x2631) to get 5034960.5Hz (32xflines) for NTSC-601. The closed-caption running clock common frequencies are detailed in [Table 1-39](#).

**Table 1-39. Closed-Caption RunClock Frequency Settings**

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[15:0] FCC field value	0x2631	0x25ED	0x2A03	0x22B6

The closed-caption data is encoded in nonreturn-to-zero (NRZ) format. Additionally, the data translates to the IRE scale as follows: 0 = 0 IRE; 1 = 50 IRE.

Figure 1-109 shows the parameters of closed-caption line data implemented in different standards.

**Figure 1-109. Closed Captioning Timing**

dss-080

**Notes:**

- The interval A is controlled by the DSS.VENC\_LN\_SEL[25:16] LN21\_RUNIN field.
- The interval B is controlled by DSS.VENC\_CC\_CARR\_WSS\_CARR[15:0] FCC field.

**Table 1-40. Closed-Caption Standard Timing Values**

Intervals	Description	Timing Values for Encoding			Timing Values for Decoding		
		Minimal	Nominal	Maximal	Lower Bound	Nominal	Upper Bound
A	HSYNC to clock running	10.250 s	10.500 s	10.750 s	10.000 s	10.500 s	11.000s
B	Clock running		12.910 s			12.910 s	
C	Clock running to third start bit		3.972 s			3.972 s	
D	Start bit		1.986 s			1.986 s	
E	Data characters		31.778 s			31.778 s	

**Note:** All timing values listed in Table 1-40 are measured from the mid-point (half amplitude) on all edges.

For a complete description of closed-caption standard, please refer to CEA-608-C standard.

### 1.4.7.6 Wide-Screen Signaling (WSS) Encoding

The encoder can embed data, encoded in accordance with the IEC61880 and ITU-R 1119 data insertion standard, within the vertical blanking interval (VBI).

The encoder supports WSS data insertion on line 20 of every frame in the NTSC format. WSS data insertion is enabled by activating the DSS.VENC\_L21\_WC\_CTL[14:13] EVEN\_ODD\_EN bit and by programming the VENC\_BSTAMP\_WSS\_DATA[27:8] WSS\_DATA field.

The running clock frequency is controlled by the DSS.VENC\_CC\_CARR\_WSS\_CARR[31:16] FWSS field. The wide-screen signaling running clock common frequencies are detailed in [Table 1-41](#)

**Table 1-41. Wide-Screen Signaling RunClock Frequency Settings**

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[31:16] FWSS field value	0x043F	0x2F72	0x04AC	0x2B6D

To select the line where the WSS data are encoded, program the DSS.VENC\_L21\_WC\_CTL[12:8] LINE field.

#### CAUTION

The setting of the LINE[4:0] field value depends on the video standard:

- PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line  $0x16 + 1 = 0x17$  (23rd line). Note that the default value is  $0x14 + 1 = 0x15$  (21st line).
- NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line  $0x10 + 4 = 0x14$  (20th line). Note that the default value is  $0x14 + 4 = 0x18$  (24th line).

The WSS encoding block assumes that a full 10-bit video range is used to determine the 70 percent of peak-white amplitude of a logic-1 bit. The encoder also supports WSS data insertion on line 23 in the PAL format. Both waveforms are shown in [Figure 1-110](#).

**Figure 1-110. WSS Timing**

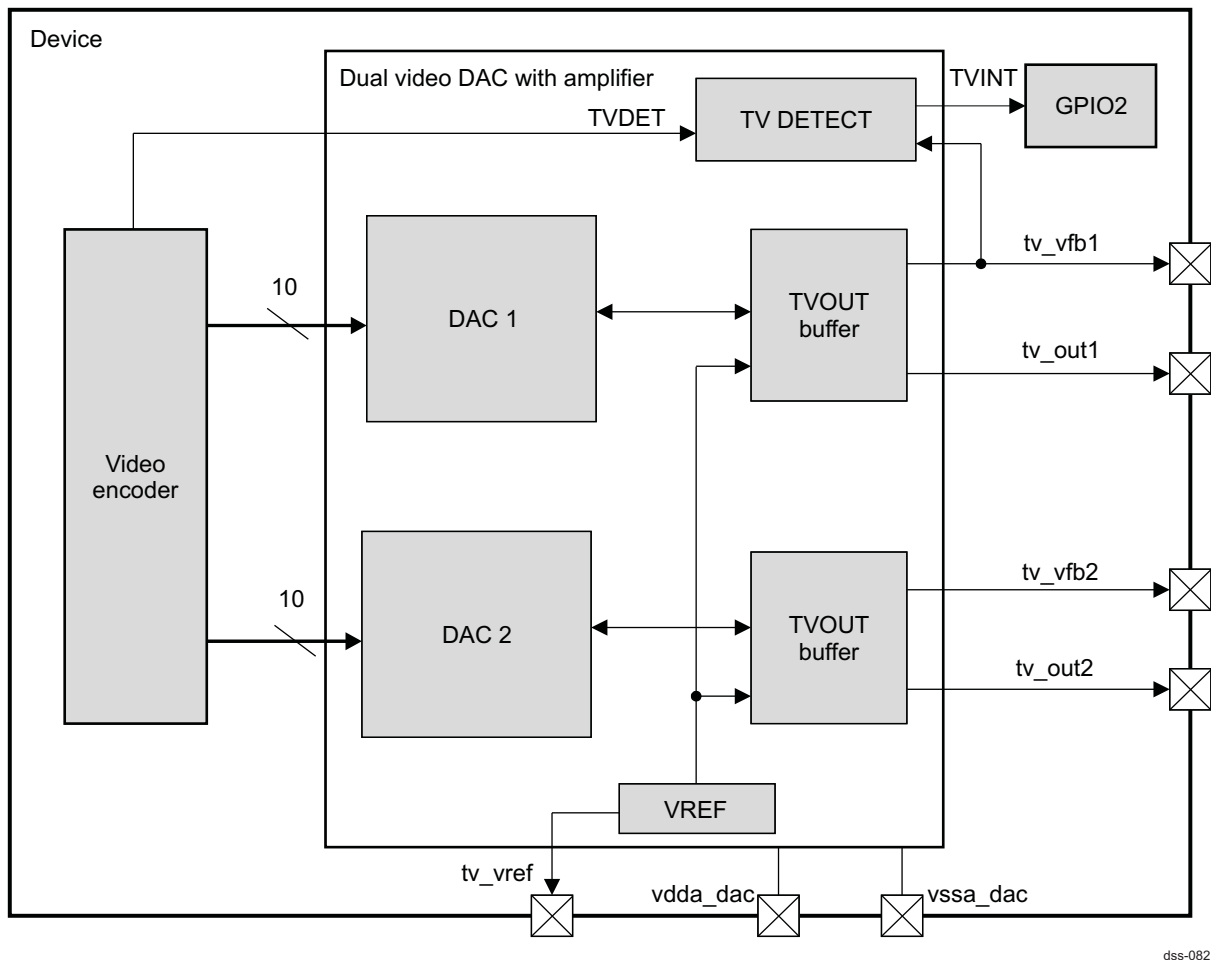

dss-081

#### 1.4.7.7 Video DAC Architecture

Figure 1-111 shows the architecture of the dual 10-bit video DAC.

Figure 1-111. Dual 10-Bit Video DAC Architecture

The display subsystem provides the necessary control signals to interface the memory frame buffer directly to external displays (TV sets). Two (one per channel) 10-bit current steering DAC is used to generate the video analog signal. The video mode DAC 1 (luma/composite) also includes the TV detection/disconnection and power-down mode features.

#### 1.4.7.8 Video DC/AC Coupled TV Load

The dual 10-bit video DAC supports both dc-coupled and ac-coupled TV loads. The CONTROL.CONTROL\_DEVCONF1[11] TVACEN bit is used to define which output coupling is used (0: Dc coupling; 1: Ac coupling). This bit is the first one to be programmed according to the TV load on the PCB board.

**Note:** When dc coupling is used, note that there is a 385-mV dc offset at the TVOUT output (tv\_out1 for DAC1 and tv\_out2 for DAC2).

#### 1.4.7.9 TV Detection/Disconnection Pulse Generation and Usage

### 1.4.7.9.1 TV Detection/Disconnection Pulse Generation

The TV detect block is an integral part of the dual video DAC module.

#### Notes:

- The TV detection/disconnection feature is supported only for VDACC1.
- The TV disconnection feature is recommended for power saving purpose. The TV detection/disconnection is only operational when video out is active. Therefore to detect cable connection automatically, it is necessary to periodically activate the video out to test for cable presence.

This block compares the output (tv\_out1) to reference (tv\_vref) voltages, to sense the condition of the load. To operate, the TV detect requires two digital signals, TVACEN and TVDET. The TVACEN signal indicates to both TVOUT buffer and the TV detect circuit if the load is ac or dc coupling to adjust accordingly. TVDET is a digital pulse at the frequency of the TV sync pulses. The operation of the circuit is based on the difference in voltage levels in the output of the buffer depending of the load status. The TV detect block compares the output against a couple of references and the result is latched at the start of every sync pulse. The status is read later in with the TVDET pulse rising edge.

The following registers are used to set the TV detection/disconnection pulse:

- The DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X register defines which pixels are used to start and stop the pulse inside their respective line.
- The DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y register defines which lines are used to start and stop the pulse.
- The DSS.VENC\_GEN\_CTRL[0] EN bit enables or disables the TVDET pulse (0: Disable; 1: Enable).
- The DSS.VENC\_GEN\_CTRL[16] TVDP bit sets the TVDET pulse polarity (0: Active low; 1: Active high).

### 1.4.7.9.2 TV Detection Procedure

The TV detection procedure is the following:

1. Initial setup:
  - Program the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
  - Set the DSS.VENC\_GEN\_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
  - Set the DSS.VENC\_GEN\_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers.
3. Set the VENC\_OUTPUT\_CONTROL[0] LUMA\_ENABLE bit (in s-video mode) or the VENC\_OUTPUT\_CONTROL[1] COMPOSITE\_ENABLE (in composite video mode) to 1 to enable the video DAC1 output.
4. Power up the VDDADAC voltage for VDACC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I<sup>2</sup>C interface connected to the power IC (TPS65950 device). For more details on the TPS65950 device, contact your TI representative.
5. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers.
6. Check the TVINT output signal: When TVINT is set to 1, the load is connected.

### CAUTION

- If ac coupling is selected, two TVDET pulses are required to set high the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If dc coupling is selected, only one TVDET pulse is required to set high the TVINT signal.

#### 1.4.7.9.3 TV Disconnection Procedure

The TV disconnection procedure is the following:

1. Initial setup:
  - Program the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
  - Set the DSS.VENC\_GEN\_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
  - Set the DSS.VENC\_GEN\_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers.
3. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers.
4. Check the TVINT output signal: When TVINT is reset to 0, the load is disconnected.
5. Reset the VENC\_OUTPUT\_CONTROL[0] LUMA\_ENABLE bit (in s-video mode) or the VENC\_OUTPUT\_CONTROL[1] COMPOSITE\_ENABLE (in composite video mode) to 0 to disable the video DAC1 output.
6. Power-down the VDDADAC voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I<sup>2</sup>C interface connected to the power IC (TPS65950 device). For more details on the TPS65950 device, contact your TI representative.

### CAUTION

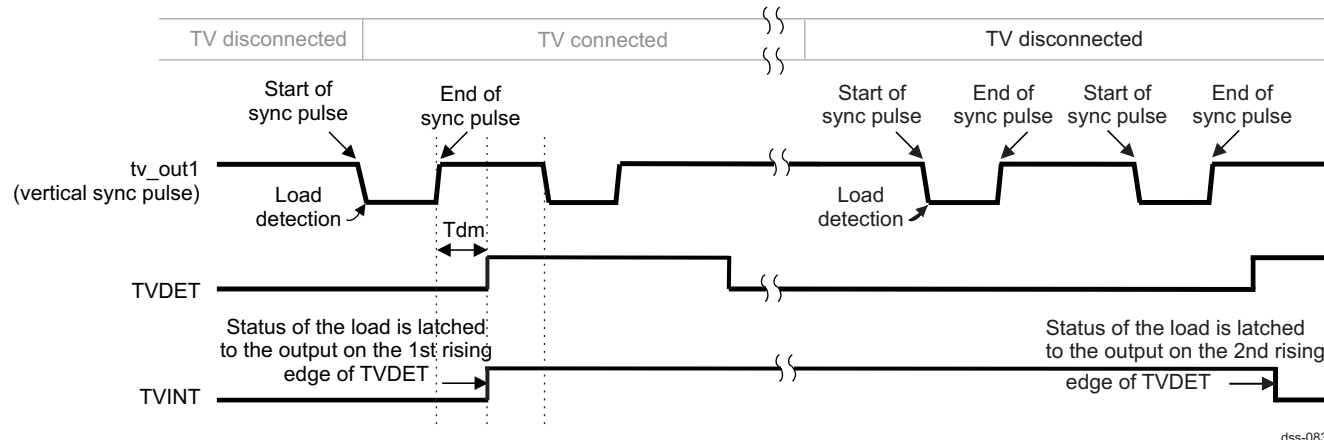

- If dc coupling is selected, two TVDET pulses are required to set low the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If ac coupling is selected, only one TVDET pulse is required to set low the TVINT signal.

#### 1.4.7.9.4 Recommended TV Detection/Disconnection Pulse Waveform

To enable the detection/disconnection of the load, the circuit requires that the TVDET pulse resembles the following waveform. As explained in [Section 1.4.7.9.2, TV Detection Procedure](#), and in [Section 1.4.7.9.3, TV Disconnection Procedure](#) by using the video encoder registers, the TVDET pulse polarity, start and stop is programmable. The only critical parameter is Tdm, which should be longer than the delay through the DAC and TVOUT buffer, which is at least 750 ns.

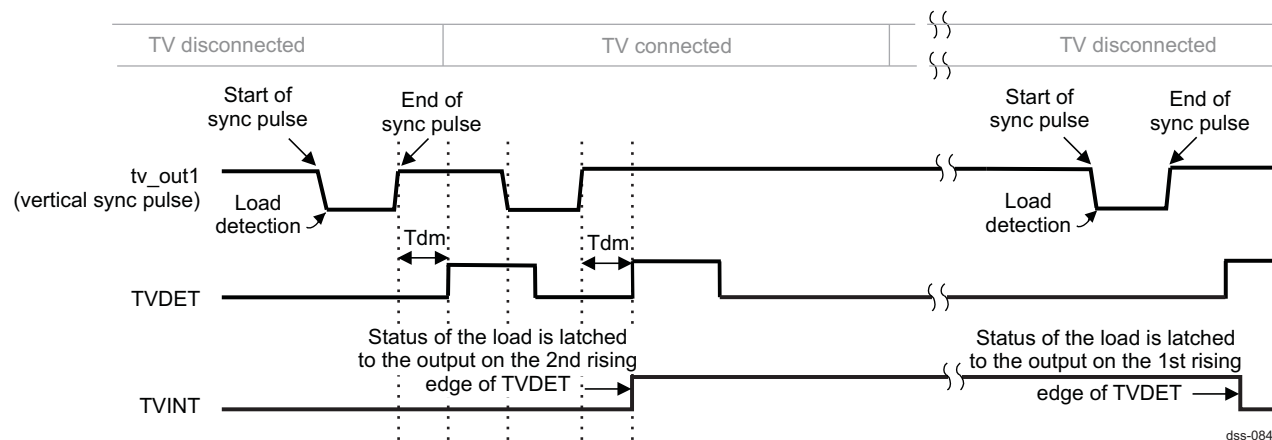

If dc-coupling is selected, the TVINT output signal for TV detection is latched at the rising edge of the first TVDET signal but the TVINT output signal for TV disconnection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing. [Figure 1-112](#) shows the waveforms for the dc-coupling TV detect pulse (TVDET) when load is connected and disconnected.

**Figure 1-112. DC-Coupling TV Detect Waveforms for TV Connected and Disconnected**

If ac-coupling is selected, the TVINT output signal for TV detection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing but the TVINT output signal for TV disconnection is latched at the rising edge of the first TVDET signal. Figure 1-113 shows the waveforms for the ac-coupling TV detect pulse (TVDET) when load is connected and disconnected.

**Figure 1-113. AC-Coupling TV Detect Waveforms for TV Connected and Disconnected**

**Notes:**

- When setting the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X register, the software user must ensure that the TVDET signal is in the active area. To avoid any problem, the TVDET signal must not be longer than one line.
- The activation of the TVDET signal will not have a visual impact on the tv\_out1 output signal.

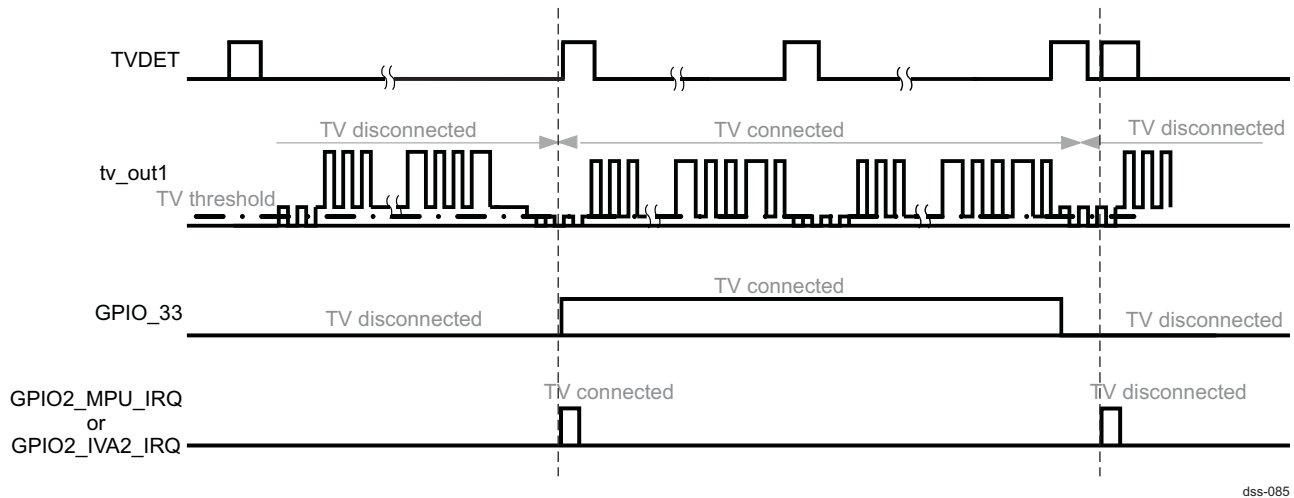

#### 1.4.7.9.5 TV Detection/Disconnection Usage

The TV-detection/TV-disconnection is based on the difference in voltage levels in the output of the TV buffer depending on the load status. The operation is slightly different for ac and for dc operation. For dc operation, the tv\_out1 voltage is compared against a voltage reference (tv\_vref) that makes the comparator trigger in each sync pulse while the load is connected. For ac operation, the tv\_out1 voltage is compared against a voltage reference (tv\_vref) that makes the comparator trigger in each sync pulse while the load is disconnected. In both cases, the TVINT output signal produces a logic 1 when a load is connected and a logic 0 when a load is disconnected.

For dc-coupling mode, see Figure 1-114 and for ac-coupling mode, see Figure 1-115

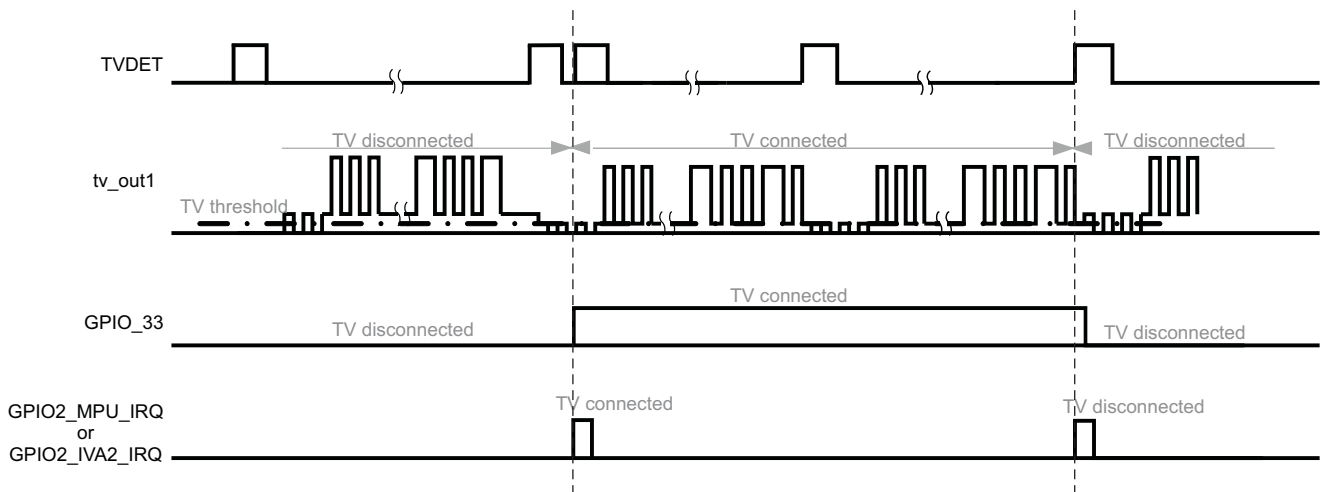

**Note:** Because the video DAC and the video encoder must be awake for connection detection, consider that the video DAC can take up to 10 s to wake up.

**Figure 1-114. GPIO Signal Waveform Proposal for TV Detection/Disconnection in DC-Coupling Mode**

dss-085

**Figure 1-115. GPIO Signal Waveform Proposal for TV Detection/Disconnection in AC-Coupling Mode**

dss-086

#### 1.4.7.10 Video DAC Bypass Mode

The dual 10-bit video DAC has a TVOUT buffer bypass mode that turns off the TVOUT buffer and redirects directly the DAC output to the VFB pins (tv\_vfb1 for DAC1 and tv\_vfb2 for DAC2).

This bypass mode is activated by setting the CONTROL.CONTROL\_DEVCONF1[18] TVOUTBYPASS bit to 1. The reset value of the CONTROL.CONTROL\_DEVCONF1[18] TVOUTBYPASS bit is 0 (that is, the TVOUT buffer is not bypassed).

**Note:** In bypass mode:

- both tv\_vfb1 and tv\_vfb2 pins require a RLOAD resistor connected to the ground. The typical value of the RLOAD resistor is 976.

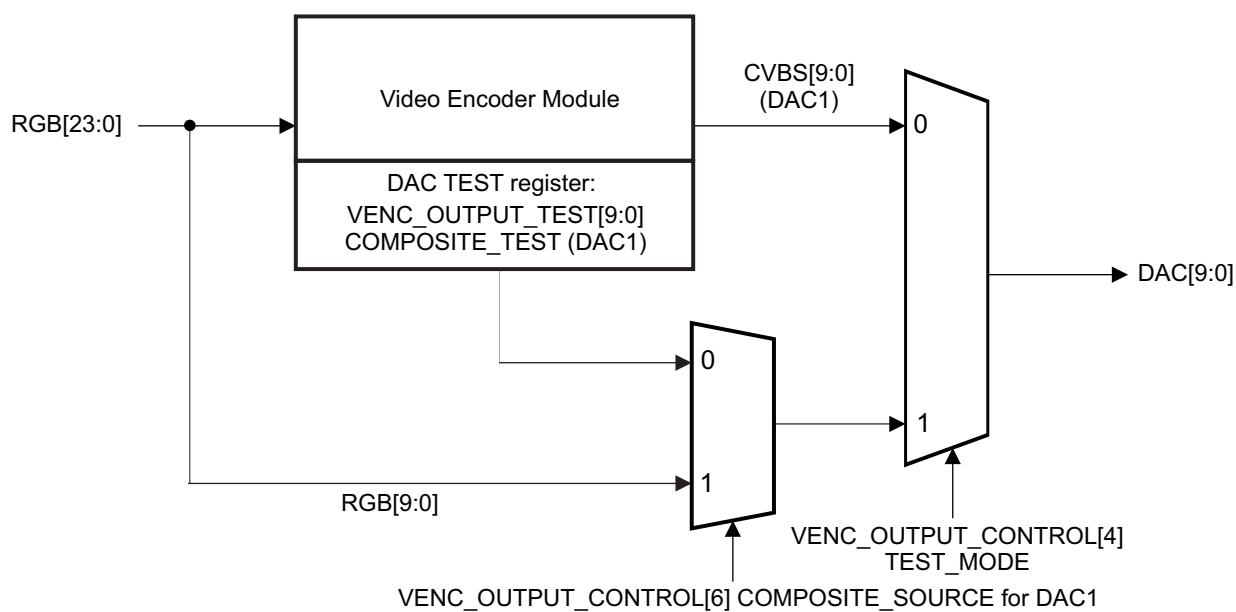

### CAUTION

- The TV detect feature is not available in bypass mode.
- In bypass mode, external amplifiers are needed on the tv\_vbf1 and tv\_vbf2 pins.

#### 1.4.7.11 Video Dual-DAC Test Mode

The DAC can be tested for debug using either 10-bit external data or 10-bit internal register values directly connected to the DAC. See [Figure 1-116](#) for video DAC test in composite video mode, and see [Figure 1-117](#) for video DAC test in separate video mode.

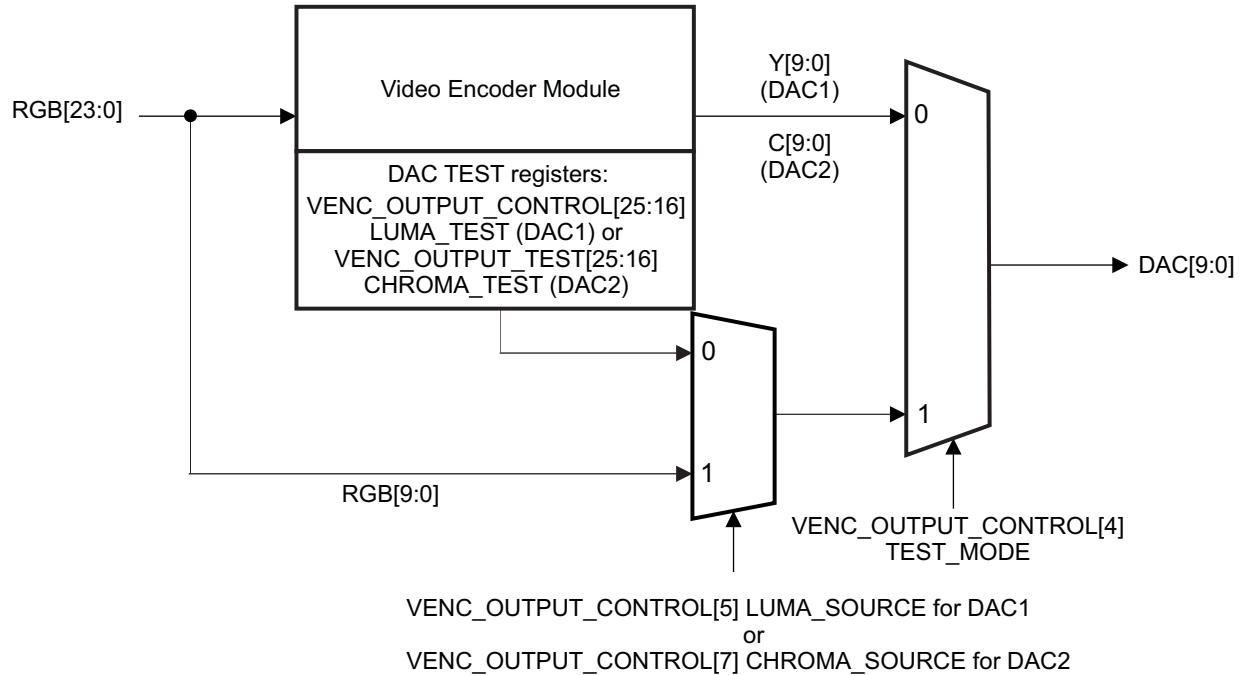

**Figure 1-116. DAC Test Mode in Composite Video Mode**

dss-087

**Figure 1-117. DAC Test Mode in Separate Video Mode**

dss-088

- Use the DSS.VENC\_OUTPUT\_CONTROL[4] TEST\_MODE bit to select between DAC normal mode (0x0) and DAC test mode (0x1).
- Use the DSS.VENC\_OUTPUT\_CONTROL[7] CHROMA\_SOURCE bit for DAC2 and either the DSS.VENC\_OUTPUT\_CONTROL[6] COMPOSITE\_SOURCE bit (in composite video mode) or the DSS.VENC\_OUTPUT\_CONTROL[5] LUMA\_SOURCE bit (in s-video mode) for DAC1 to select the test mode:
  - 0x0: From the internal register DSS.VENC\_OUTPUT\_TEST[25:16] CHROMA\_TEST bit field for DAC2 and either DSS.VENC\_OUTPUT\_TEST[9:0] COMPOSITE\_TEST bit field (composite video) or DSS.VENC\_OUTPUT\_CONTROL[25:16] LUMA\_TEST (s-video mode) for DAC1
  - 0x1: From the video port G[1:0], B[7:0]

**Note:** In the external data test mode (bypass mode), the display controller must provide the data (G[1:0], B[7:0]) externally. To do this, configure the video encoder to generate correct timing signals, without which the display controller cannot operate (even if the encoder core is bypassed from the data path perspective).

### 1.4.8 SDI Functionalities

This section describes SDI module. This module is not available on all devices. See Chapter 1, the *OMAP35x Family* section, to check availability of this module.

The SDI interface has three main functions:

- A PLL (SDI\_PLL) to multiply or divide the pixel clock frequency (PCLK) up to the required data rate. The pixel clock frequency range is 4-65 MHz. This clock may be divided by 2 above 32 MHz to meet the PLL input reference timing requirements.
- A specific IP block to output the data in the chosen serial format
- Output buffers to transmit the small swing differential signals

The last two functions are combined in the complex I/O module. [Figure 1-118](#) shows the SDI architecture.

The diagram illustrates the internal architecture of the Serial display interface (SDI) complex I/O. It shows the flow of data and control signals between the display controller, the display subsystem, and the external display device.

**Inputs from the display controller and subsystem:**

- Control signals** and **Pixel data[17:0]** are sent to the **Re-synchronizer**.
- Configuration from the display subsystem** is sent to the **Re-synchronizer**, **Clock generator**, and **Serializer**.
- High-speed clock** is sent to the **Clock generator**.
- PCLK** is sent to the **SDI\_PLL**.

**Internal Components and Signal Flow:**

- The **Re-synchronizer** outputs to the **Serializer**.
- The **Clock generator** outputs to the **Serializer** and the **SDI\_PLL**.
- The **SDI\_PLL** outputs **LOCK**, **RECAL**, and **PCLK** signals.
- The **Serializer** outputs **CMOS signals for pin multiplexing** to the external display device.

**Outputs to the external display device:**

- DA (Data)** signals are sent to the display device.
- CL (Clock)** signals are sent to the display device.
- A **Dedicated FlatLink3G switch ground** is provided.

- The SDI\_ERROR status indicated when the SDI module is in error mode (0: No error; 1: SDI in error). This status allows monitoring error conditions, such as inconsistent configuration or internal loss of synchronization. It is connected to the GPIO\_82 internal signal of the GPIO3 module. For additional information, see the *General-Purpose Interface* chapter.

## 1.5 Display Subsystem Basic Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI, the SDI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)  
Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.
- TV set support  
Configure the video encoder and then the display controller.
- Both LCD panel support (bypass or RFBI mode) and TV set support  
Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.
- TI FlatLink 3G-compliant LCD panel support  
Configure the SDI, configure the video encoder, and then configure the display controller.

### 1.5.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. If the LCD is on, stop the LCD by setting the DSS.DISPC\_CONTROL[0] LCDENABLE bit to 0.
  - a. Reset the frame done status bit by writing 1 in the DSS.DISPC\_IRQSTATUS[0] FRAMEDONE bit.
  - b. Wait until the DSS.DISPC\_IRQSTATUS[0] FRAMEDONE bit is set to 1. This shows that the end of frame has taken place and the LCD stop is complete.
2. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
  - PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit set to 1
  - PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit set to 1
  - PRCM.CM\_FCLKEN\_DSS[2] EN\_TV bit set to 1
  - PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit set to 1
 Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
3. Write 1 in the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit to apply the soft reset to the subsystem.
4. Read the DSS.DSS\_SYSSTATUS[0] RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

### 1.5.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.DSS\_CONTROL[0] DSS\_CLK\_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.DSS\_CONTROL[2] VENC\_CLOCK\_MODE bit and the DSS.DSS\_CONTROL[3] VENC\_CLOCK\_X4 bit for TV set support.
3. To configure the top level of the DAC, set the DSS.DSS\_CONTROL[4] DAC\_DEMEN bit for TV set support (if required).
4. Configure the TI FlatLink 3G-compliant LCD panel through the SPI interface to use the serial interface display.
5. Configure the RFBI module and/or the SDI module and/or the video encoder as needed.
6. Configure the display controller.

### 1.5.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.DISPC\_CONTROL[5] GOLCD bit is set for the LCD output and/or the DSS.DISPC\_CONTROL[6] GODIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.DISPC\_CONTROL[6] GODIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.DISPC\_CONTROL[5] GOLCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.DISPC\_CONTROL[5] GOLCD or DSS.DISPC\_CONTROL[6] GODIGITAL bit, ensure that the bit is cleared.

Table 1-42 lists the shadow registers.

**Table 1-42. Shadow Registers**

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_CONTROL	X <sup>(1)</sup>	X <sup>(1)</sup>
DSS.DISPC_CONFIG	X	X
DSS.DISPC_DEFAULT_COLOR <sub>m</sub> (m = 0)	X	
DSS.DISPC_DEFAULT_COLOR <sub>m</sub> (m = 1)		X
DSS.DISPC_TRANS_COLOR <sub>m</sub> (m = 0)	X	
DSS.DISPC_TRANS_COLOR <sub>m</sub> (m = 1)		X
DSS.DISPC_LINE_NUMBER	X	
DSS.DISPC_TIMING_H	X	
DSS.DISPC_TIMING_V	X	
DSS.DISPC_POL_FREQ	X	
DSS.DISPC_DIVISOR	X	
DSS.DISPC_SIZE_DIG		X
DSS.DISPC_SIZE_LCD	X	
DSS.DISPC_GFX_BA <sub>j</sub> (j = 0,1)	X	X
DSS.DISPC_GFX_POSITION	X	X
DSS.DISPC_GFX_SIZE	X	X
DSS.DISPC_GFX_ATTRIBUTES	X	X
DSS.DISPC_GFX_FIFO_THRESHOLD	X	X
DSS.DISPC_GFX_ROW_INC	X	X
DSS.DISPC_GFX_PIXEL_INC	X	X
DSS.DISPC_GFX_WINDOW_SKIP	X	X
DSS.DISPC_GFX_TABLE_BA	X	X
DSS.DISPC_GFX_PRELOAD	X	X
DSS.DISPC_CPR_COEF_R	X	
DSS.DISPC_CPR_COEF_G	X	
DSS.DISPC_CPR_COEF_B	X	
DSS.DISPC_VID <sub>n</sub> _BA <sub>j</sub> (j = 0,1)	X	X
DSS.DISPC_VID <sub>n</sub> _POSITION	X	X
DSS.DISPC_VID <sub>n</sub> _SIZE	X	X

<sup>(1)</sup> Some of the register bit fields are shadow bits. For more information, see [Section 1.7, Display Subsystem Registers](#).

**Table 1-42. Shadow Registers (continued)**

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_VIDn_ATTRIBUTES	X	X
DSS.DISPC_VIDn_FIFO_THRESHOLD	X	X
DSS.DISPC_VIDn_ROW_INC	X	X
DSS.DISPC_VIDn_PIXEL_INC	X	X
DSS.DISPC_VIDn_FIR	X	X
DSS.DISPC_VIDn_PICTURE_SIZE	X	X

DSS.DISPC_VIDn_FIR_COEF_Hi (i = 0 to 7)	X	X
DSS.DISPC_VIDn_FIR_COEF_HVi (i = 0 to 7)	X	X
DSS.DISPC_VIDn_FIR_COEF_Vi (i = 0 to 7)	X	X
DSS.DISPC_VIDn_CONV_COEFi (i = 0 to 4)	X	X
DSS.DISPC_VIDn_PRELOAD	X	X
DSS.DISPC_DATA_CYCLEk (k = 0 to 3)	X	

### 1.5.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC\_SYSCONFIG
- DSS.DISPC\_SYSSTATUS
- DSS.DISPC\_IRQSTATUS
- DSS.DISPC\_IRQENABLE

### 1.5.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

#### 1.5.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC\_CONTROL
- DSS.DISPC\_GFX\_BA<sub>j</sub>
- DSS.DISPC\_GFX\_ATTRIBUTES
- DSS.DISPC\_GFX\_ROW\_INC
- DSS.DISPC\_GFX\_PIXEL\_INC
- DSS.DISPC\_GFX\_FIFO\_THRESHOLD
- DSS.DISPC\_GFX\_TABLE\_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC\_GFX\_ATTRIBUTES[0] GFXENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC\_GFX\_ATTRIBUTES[7:6] GFXBURSTSIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC\_GFX\_ATTRIBUTES[11] GFXFIFOPRELOAD bit): The default

preload configuration uses the DSS.DISPC\_GFX\_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC\_GFX\_ATTRIBUTES[11] GFXFIFOPRELOAD bit, the software user selects between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

- Active matrix (TFT) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0x60 (value is 96)
- Color passive matrix (STN) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0x72 (value is 114)
- Monochrome passive matrix (STN) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0xE0 (value is 224)
- Base address of the graphics buffer in system memory (DSS.DISPC\_GFX\_BA<sub>j</sub> registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register DSS.DISPC\_GFX\_BA0 defines the base address of the even field; and DSS.DISPC\_GFX\_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC\_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD register): The low threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC\_CONFIG[14] FIFOMERGE bit to 1, the software user merges the three FIFOs (GFX, VID1 and VID2) into a single one. In this case, the low (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values must be programmed with a multiplier factor of three (3 x value). Note that by default the FIFOs are not merged (DSS.DISPC\_CONFIG[14] FIFOMERGE bit reset value is 0).
- Palette/gamma table used (DSS.DISPC\_CONFIG[3] PALETTEGAMMATABL bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (DSS.DISPC\_GFX\_TABLE\_BA register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

---

**Note:** In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

---

- Graphics Priority (DSS.DISPC\_GFX\_ATTRIBUTES[14] GFXARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For e.g. pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (DSS.DISPC\_GFX\_ATTRIBUTES[15] GFXSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

### 1.5.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- DSS.DISPC\_CONFIG
- DSS.DISPC\_GFX\_POSITION
- DSS.DISPC\_GFX\_SIZE
- DSS.DISPC\_GFX\_ATTRIBUTES

The graphics layer is enabled/disabled by setting/resetting the DSS.DISPC\_GFX\_ATTRIBUTES[0] GFXENABLE bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the DSS.DISPC\_CONTROL[6] GODIGITAL or DSS.DISPC\_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

### 1.5.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format (DSS.DISPC\_GFX\_ATTRIBUTES[4:1] GFXFORMAT field): The default value of this field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position (DSS.DISPC\_GFX\_POSITION[10:0] GFXPOSX field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position (DSS.DISPC\_GFX\_POSITION[26:16] GFXPOSY field): The default value of this field at reset time is 0x0. The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width (DSS.DISPC\_GFX\_SIZE[10:0] GFXSIZEX field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the DSS.DISPC\_GFX\_ATTRIBUTES[7:6] GFXBURSTSIZE field (in bytes).

---

**Note:** When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC\_GFX\_ROW\_INC register is not 1. When DSS.DISPC\_GFX\_ROW\_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

---
